

The frequency of growth takeoffs in low-income countries (LICs) has risen markedly during the past two decades, and these takeoffs have lasted longer than those that took place before the 1990s. Economic structure has not mattered much in sparking takeoffs—takeoffs have been achieved by LICs rich in resources and by those oriented toward manufacturing. A striking similarity between recent takeoffs and those before the 1990s is that they have been associated with higher investment and national saving rates and with stronger export growth, which sets them apart from LICs that were unable to take off and confirms the key role of capital accumulation and trade integration in development. However, recent takeoffs stand out from earlier takeoffs in two important aspects. First, today's dynamic LICs have achieved strong growth without building macroeconomic imbalances—as reflected in declining inflation, more competitive exchange rates, and appreciably lower public and external debt accumulation. For resource-rich LICs, this has been due to a much greater reliance on foreign direct investment (FDI). For other LICs, strong growth was achieved despite lower investment levels than in the previous generation. Second, recent takeoffs are associated with a faster pace of implementing productivity-enhancing structural reforms and strengthening institutions. For example, these LICs have a lower regulatory burden, better infrastructure, higher education levels, and greater political stability. Looking forward, there remain many challenges to maintaining strong growth performance in today's dynamic LICs, including the concentration of their growth in only a few sectors and the need to diversify their economies, and ensuring that growth leads to broad-based improvements in living standards. Still, if these countries succeed in preserving their improved policy foundation and maintaining their momentum in structural reform, they seem more likely to stay on course and avoid the reversals in economic fortunes that afflicted many dynamic LICs in the past.

The authors of this chapter are John Bluedorn, Rupa Duttagupta (team leader), Jaime Guajardo, Nkunde Mwase, Shan Chen, and Angela Espiritu. Many helpful suggestions were provided by Andrew Berg, Romain Duval, Andrew Levin, Chris Papageorgiou, and Catherine Pattillo.

Introduction

LICs have made a comeback during the past two decades (Figure 4.1). Growth in their output per capita rebounded beginning in the 1990s. Furthermore, they have grown at a faster pace than advanced economies since the turn of the 21st century and have even outpaced other emerging market and developing economies since the Great Recession.¹ Could this be the beginning of a new era for LIC growth and convergence?

For skeptics, however, this comeback evokes the 1960s and early 1970s, when LIC growth looked promising, only to disappoint when global economic conditions turned sour in the 1980s. LICs' subsequent economic deceleration induced deep pessimism about their prospects, and many wondered if they could escape poverty and economic divergence given their weak institutions, unimpressive economic reform, and resource-curse issues.² Is the recent comeback just déjà vu?

This chapter sheds light on the above debate by analyzing growth takeoffs in LICs during the past 60 years and comparing takeoffs beginning in the 1990s with those in earlier decades. It assesses whether recent takeoffs are less vulnerable than in the past, improving LICs' ability to take off and rise out of poverty even in a sluggish world economy. Specifically, the chapter addresses the following questions:

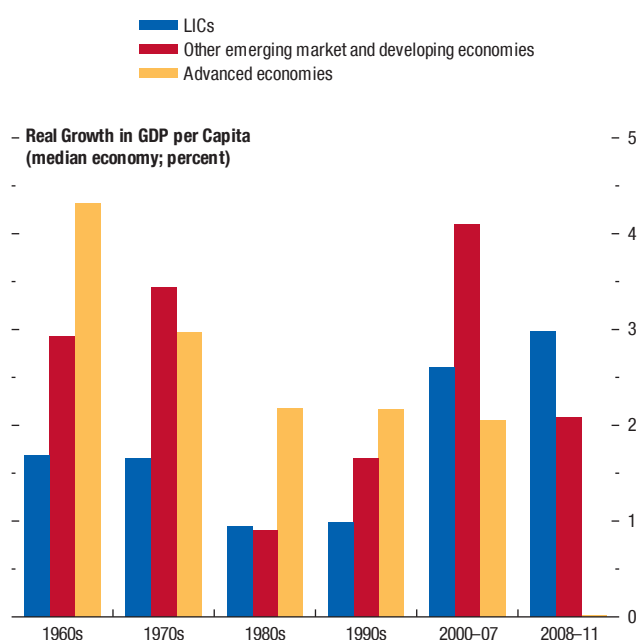

- How do recent growth takeoffs in LICs compare with those of the past? Are they stronger? Have they lasted longer?
- What has changed in the economic and structural conditions and policies of LICs that have taken off since the 1990s compared with those that took off in the past? For both eras, what separated LICs that launched a takeoff from those that did not?

¹Some studies have also noted the recent increased persistence of LIC growth. See Chapters 2 and 3, respectively, of the October 2008 and April 2011 *Regional Economic Outlook: Sub-Saharan Africa* reports.

²See Pritchett (1997), Sachs and Warner (1997, 2001), Easterly and Levine (1997), and Rodrik (1999).

Figure 4.1. Economic Performance of Low-Income Countries and Others

Low-income countries (LICs) have seen a major improvement in their economic performance since the 1990s. Growth in output per capita for the median LIC has increased since the 1990s. It is now higher than median growth in other economy groups.

Sources: IMF, World Economic Outlook database (October 2012); Penn World Table 7.1; World Bank, World Development Indicators database; and IMF staff calculations. Note: Economy groups and indicators are defined in Appendix 4.1. Real GDP per capita is in purchasing-power-parity terms. The 2008–11 median of real GDP per capita growth of advanced economies is near zero (0.02 percentage point).

- Can historical experience shed further light on specific policies that can help LICs ignite and sustain growth takeoffs?
- What are the key policy lessons for today’s LICs?

This chapter addresses these questions by examining the nature of growth takeoffs in more than 60 LICs since the 1950s. It first defines and identifies LIC growth takeoffs and compares the strength of these takeoffs from a historical perspective. It then uses statistical associations and multivariate estimations to gauge the differences in the economic conditions and policies in LICs that experienced growth takeoffs since the 1990s compared with LICs that took off in earlier periods, and between today’s dynamic LICs and their counterparts that could not take off. The analysis then zooms in on country-specific experiences to draw lessons for today’s LICs. The chapter concludes by assessing the economic prospects for LICs.

LIC Takeoffs in Historical Perspective

This section identifies growth takeoffs in LICs during the past two decades and compares them with earlier takeoffs.³ A growth takeoff is identified as an upswing in LIC output per capita that lasts at least five years, with average annual growth in real output per capita during the upswing of at least 3.5 percent. The Harding and Pagan (2002) methodology is used to pick turning points in each LIC’s annual level of purchasing-power-parity (PPP)-adjusted real GDP per capita from 1950 to 2011 and then to identify the upswings.⁴ The threshold of 3.5 percent growth is the 60th percentile of growth in output per capita in all emerging market and developing economies over the past two decades and is the standard threshold used in

³Throughout the chapter, growth is expressed in terms of growth in PPP-adjusted real GDP per capita. Advanced economies correspond to the member economies of the Organization for Economic Cooperation and Development as of 1990, with the exception of Turkey. All other economies are classified as emerging market and developing economies (EMDEs). At any given time, an LIC is defined as an economy whose average real output per capita over the previous five years is lower than a time-varying low-income threshold. The low-income threshold in 1990 is set at the bottom 45th percentile of average EMDE output per capita (about \$2,600 in PPP-adjusted constant 2005 U.S. dollars). This threshold is extrapolated backward and forward using the average growth rate of global output per capita during 1950–2011 (about 2.3 percent per year) to get a low-income threshold for each year. To ensure that the results are unaffected by very small economies, the sample excludes economies whose average 1950–2011 population was less than 1 million. China and India are included in EMDEs, but not LICs.

⁴See Appendix 4.1 for a description of the methodology.

Note: The table lists emerging market and developing economies that started with real output per capita (purchasing-power-parity-adjusted constant 2005 U.S. dollars) below the time-varying threshold at the beginning of the episode and grew at an average rate of 3.5 percent or higher for at least five years at any time since 1990. See Appendix 4.1 for details on how the economic structure classifications are derived. Countries in red were experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See Appendix 4.1 for the definition of conflict and the source of the conflict data.

¹Ongoing takeoffs as of 2011 are left blank.

²Ongoing takeoffs as of 2011 use duration as of 2011.

³Ongoing takeoffs as of 2011 use average growth as of 2011.

⁴Countries are also validly classified as predominantly nonrenewable resource and forestry producers.

other studies.⁵ The window of five years is long enough to rule out one-time increases in growth in output per capita within shorter periods. Together, these criteria identify 29 growth takeoffs during 1990–2011 (Table 4.1) and 41 episodes in earlier decades (Table 4.2).⁶

The frequency of LICs starting or sustaining a takeoff has increased since 1990. Figure 4.2, panel 1, shows the number and share of LICs that embarked

on a takeoff each year and confirms an increase in this frequency since the late 1990s.

Panel 2 shows the total number and share of LICs that either took off or sustained an ongoing takeoff. It suggests that there were two waves of takeoffs, one from the mid-1960s to the early 1970s and one beginning in the 1990s. The frequency of growth takeoffs declined after 2008, in part because of data censoring, but also because of a drop in the share of LICs that had sustained their takeoffs.⁷ Nevertheless, despite the Great Recession, one-third of LICs still sustained their takeoffs as of 2011 compared with an average of 20 percent during the 1980s.

Takeoffs since the 1990s have lasted longer than those in the previous generation (Figure 4.2, panel 3). Over the past two decades, the median duration was 9 years for growth episodes that were already completed and 12 years for episodes that were still ongoing as of

⁷Given the criterion that a takeoff must last at least five years, it is not possible to identify new takeoffs that began after 2007.

⁵See Hausmann, Pritchett, and Rodrik (2005) and Johnson, Ostry, and Subramanian (2007). The empirical results hold for modifications to the definition for low-income (for instance, a fixed low-income threshold) or to the criteria for identifying takeoffs (for example, a higher growth threshold or a longer-lived upswing). See Appendices 4.2 and 4.3 for details.

⁶Some of these episodes followed serious internal or external conflicts and were excluded from the analysis (see Appendix 4.1 for the definition of a postconflict takeoff). However, the results hold even with the inclusion of postconflict cases. Note also that some of the episodes in Tables 4.1 and 4.2 would be considered to be of longer duration if short-lived breaks between episodes for the same country were excluded. The empirical results of the chapter are broadly unchanged with an alternative definition of growth takeoffs that allows for such breaks. See Appendices 4.2 and 4.3 for details.

2011. Before 1990, the median duration of a takeoff was seven years. Median growth in output per capita was 6¼ percent and 5¼ percent, respectively, in ended and ongoing takeoffs over the past two decades, compared with about 5 percent for takeoffs before 1990.

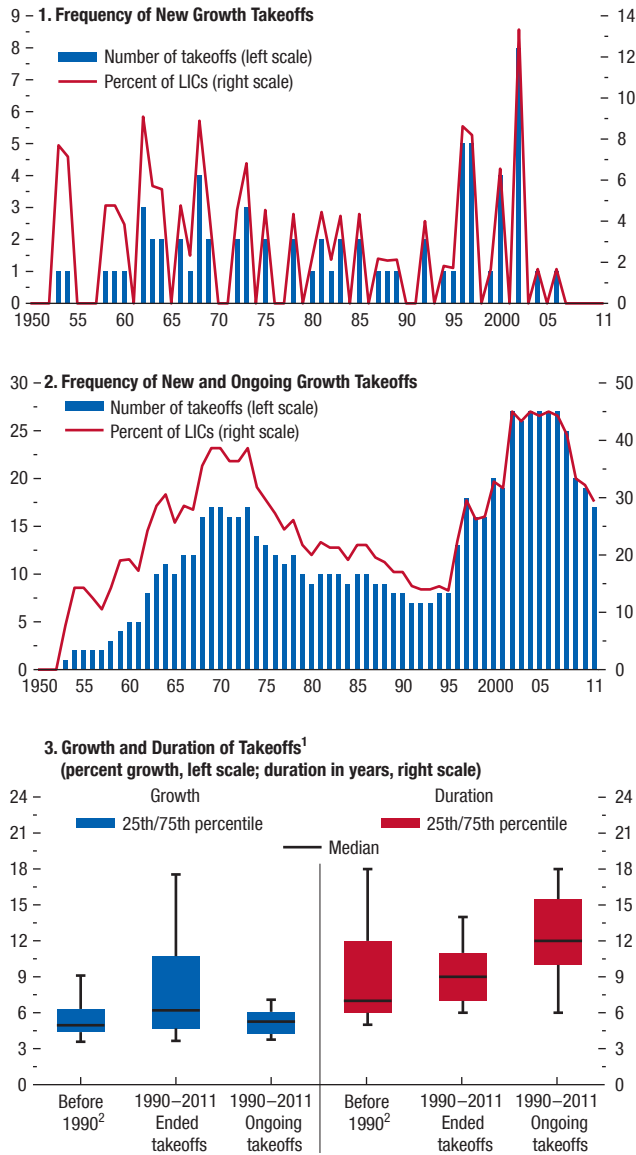

Global conditions helped spur LIC takeoffs, but there was obviously more at play. Figure 4.3 documents the behavior of global growth, the U.S. real interest rate as a proxy for global interest rates, and terms-of-trade growth underlying LIC takeoffs before and after the 1990s. Each global indicator is presented in three snapshots: its average level during the five years before

takeoff, five years after takeoff, and during years six to ten after takeoff.⁸ Compared with pre-1990 takeoffs, recent takeoffs started under weaker global growth and higher global interest rates. However, global growth and interest rate conditions tended to improve after takeoff for the current generation, whereas they deteriorated for the previous generation. Terms-of-trade growth before takeoff was more favorable for the former than the latter, although terms-of-trade growth rose for both

⁸Global growth and interest rates are expressed as deviations from their average value during the entire sample period (1950–2011).

Figure 4.2. Frequency of New and Ongoing Takeoffs in Low-Income Countries

The share of low-income countries (LICs) starting and sustaining growth takeoffs increased sharply beginning in the 1990s. Nearly one-third of LICs were still sustaining a takeoff in 2011 despite the Great Recession. On average, takeoffs during the past two decades have been stronger and longer than those before the 1990s.

Sources: IMF, World Economic Outlook database (October 2012); Penn World Table 7.1; World Bank, World Development Indicators database; and IMF staff calculations.
 Note: Economy groups and indicators are defined in Appendix 4.1. See the text for definitions of new and ongoing growth takeoffs.

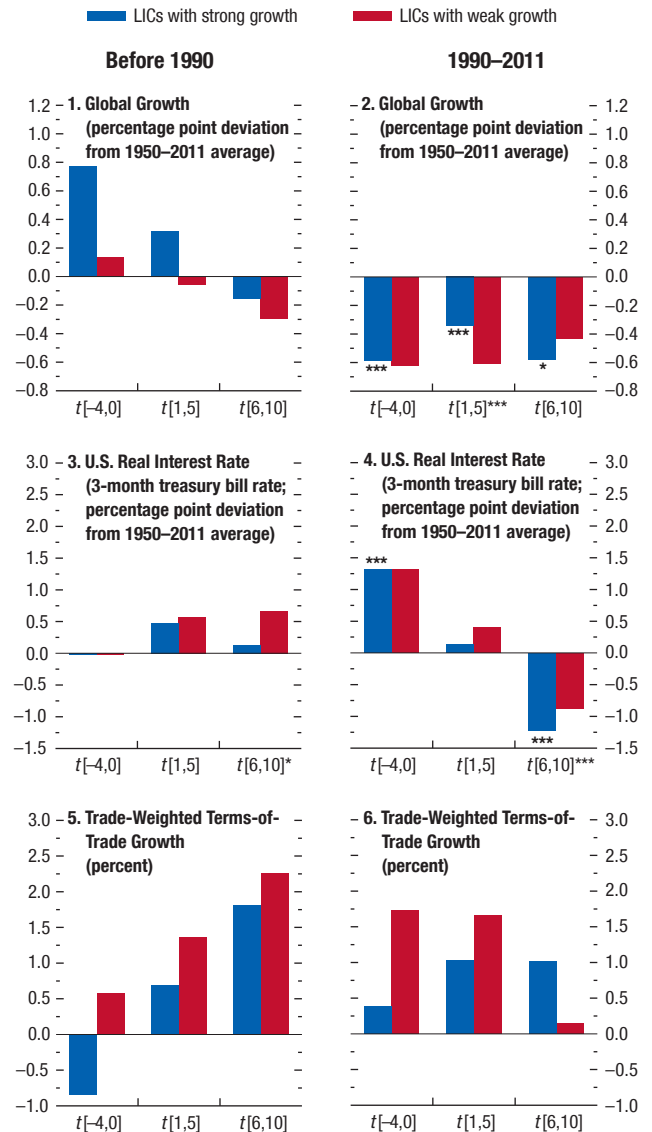

¹The horizontal line inside each box is the median within the group; the upper and lower edges of each box show the top and bottom quartiles. The distance between the black lines (adjacent values) above and below the box indicates the range of the distribution within that generation, excluding outliers.

²The episodes before 1990 include one ongoing takeoff (Vietnam since 1981).

Figure 4.3. The Global Environment behind Low-Income Countries' Growth Takeoffs

(Median economy; $t = 1$ in the first year of a strong or weak growth episode)

Global growth and interest rate conditions tended to improve after takeoff for the current generation, whereas they deteriorated for the previous generation. Terms-of-trade growth tended to improve during takeoffs for both generations.

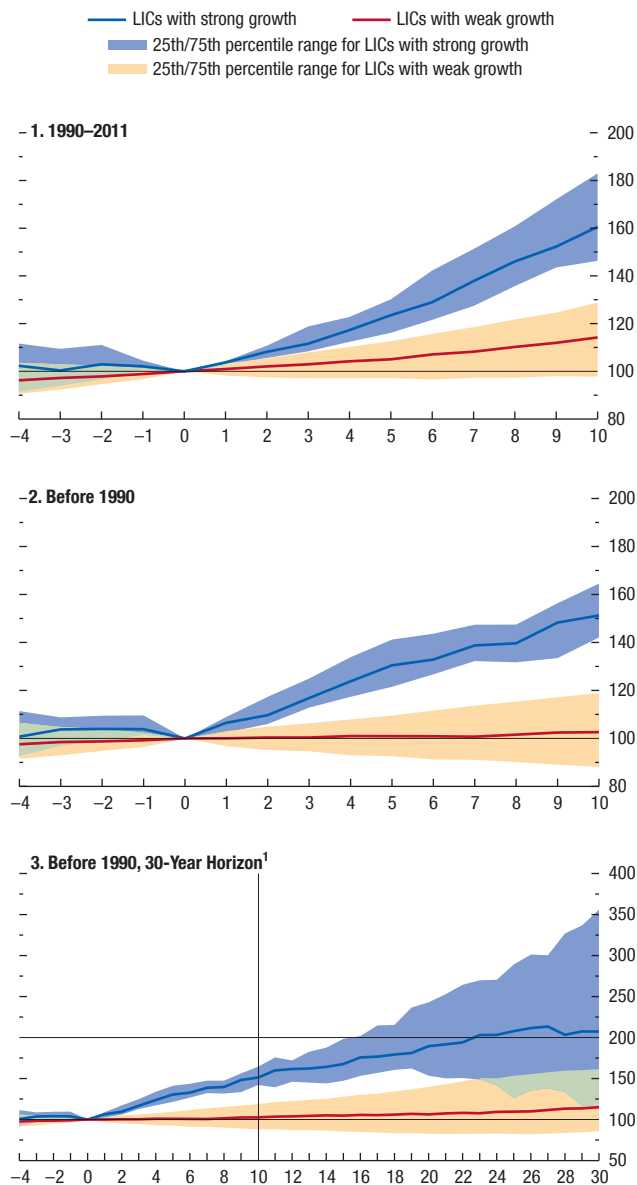

Sources: Haver Analytics; IMF, World Economic Outlook database (October 2012); Penn World Table 7.1; World Bank, World Development Indicators database (2012); and IMF staff calculations.

Note: LICs = low-income countries. Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data. *, **, and *** denote statistically significant difference in distributions (based on the Kolmogorov-Smirnov test) at the 10 percent, 5 percent, and 1 percent levels, respectively. Significance tests on the x-axis are for the difference in the distributions between the groups of strong and weak growth. Significance tests on the blue bars are for the difference in the distributions across 1990-2011 and before 1990 (not shown for red bars). A constant composition sample underlies each of the panels to ensure comparability within the group of strong and weak growth episodes across time for that panel.

Figure 4.4. Real Output per Capita after Takeoff in Low-Income Countries
(Median economy; normalized to 100 at t = 0, the year before the start of a strong or weak growth episode; years on x-axis)

Output per capita tended to stay on a higher trajectory for low-income countries (LICs) that succeeded in taking off, compared with those that did not. It typically increased by 60 percent during the 10 years after takeoff for the current generation of dynamic LICs and by 50 percent for the previous generation. This compares with an increase of less than 15 percent for the LICs that were unable to take off for the current generation and less than 5 percent for the previous generation. However, some dynamic LICs in the previous generation experienced reversals in output per capita growth within 20 years of takeoff.

Source: IMF staff calculations.
 Note: Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data.
¹The vertical line indicates the 10-year horizon.

generations after takeoff. That said, LICs that were unable to take off faced similar global conditions as those that did, suggesting that domestic conditions and policies also affect whether or not an LIC takes off.

Igniting takeoffs pays off in long-term gains in output per capita. Figure 4.4 shows that LICs that succeeded in taking off tended to remain on a stronger trajectory for output per capita in the years after takeoff.⁹ For the current generation, output per capita increased by 60 percent over the 10 years following takeoff, compared with about 15 percent for LICs with weaker growth (Figure 4.4, panel 1). For the previous-generation dynamic LICs, output per capita typically increased by 50 percent 10 years after takeoff and doubled within 25 years (Figure 4.4, panels 2 and 3).

LICs that took off had a variety of economic structures, with some rich in resources and others focused on manufacturing. The same holds for their peers that did not take off. Among the current generation of takeoffs, the resource-rich LICs performed particularly well—their GDP per capita typically rose by 80 percent in 10 years—but many of their resource-rich peers could not jump-start growth (Figure 4.5, panels 1 and 2). Among dynamic LICs prior to 1990, resource-rich LICs tended to perform strongly in the first 10 years after takeoff but were overtaken after 10 years by other LICs (Figure 4.5, panel 3). Among past weak performers, resource-rich LICs in fact experienced the slowest growth (Figure 4.5, panel 4).¹⁰ Manufacturing-oriented dynamic LICs among both the current and previous generation of takeoffs saw a 50 percent rise in GDP per capita after 10 years. But many of their manufacturing-oriented peers were unable to take off.

History tells a cautionary tale for LICs today. First, many currently dynamic LICs also belonged to the previous cohort of dynamic LICs, which raises questions about whether the vulnerabilities of these LICs have changed fundamentally. Second, close to one-third of previous takeoffs ended with a currency, debt, or banking crisis (Table 4.3). Although fewer of the recent takeoffs have ended with crises thus far (less than

⁹In Figure 4.4, the year before the start of each growth takeoff is centered at zero. The control group includes country-year pairs of LICs that did not experience a new or ongoing growth takeoff in the years in which the dynamic LICs took off.

¹⁰The poor performance of resource-rich economies in earlier decades confirms the conventional wisdom about the unintended consequences of resource abundance—the so-called resource curse manifested in Dutch disease, rent seeking, and extractive political regimes (IMF, 2012b; Iimi, 2007). What is most striking is that a group of resource-rich LICs was able to overcome the curse and take off.

Table 4.3. Crises and the Ends of Growth Takeoffs in Low-Income Countries, 1970–2011

Country	Takeoff Start	Takeoff End	Crisis ¹

Sources: Laeven and Valencia (2012); and IMF staff calculations.

Note: Countries shown in red were experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See Appendix 4.1 for the definition of conflict and the source of the conflict data.

¹Growth takeoffs are shown if their end year is coincident with a financial crisis, a financial crisis occurred in the previous two years, or a financial crisis occurred in the following two years. A financial crisis is a banking, currency, or sovereign debt crisis, taken from Laeven and Valencia (2012). Over the period 1970–89, 32 percent of growth takeoffs (either ended or ongoing) were associated with a financial crisis near their end. Over the period 1990–2011, the corresponding incidence was only 14 percent.

15 percent), their future prospects remain uncertain. Finally, Figure 4.4, panel 3, shows that the pace of growth in the previous generation of takeoffs slowed after 10 years, and that the output per capita of dynamic LICs in the bottom quartile of the distribution began to reverse its gains within 20 years after takeoff. Is the current generation of takeoffs vulnerable to similar reversals? The next section addresses this question.

What Lies within: The Role of Economic and Structural Policies and Institutions

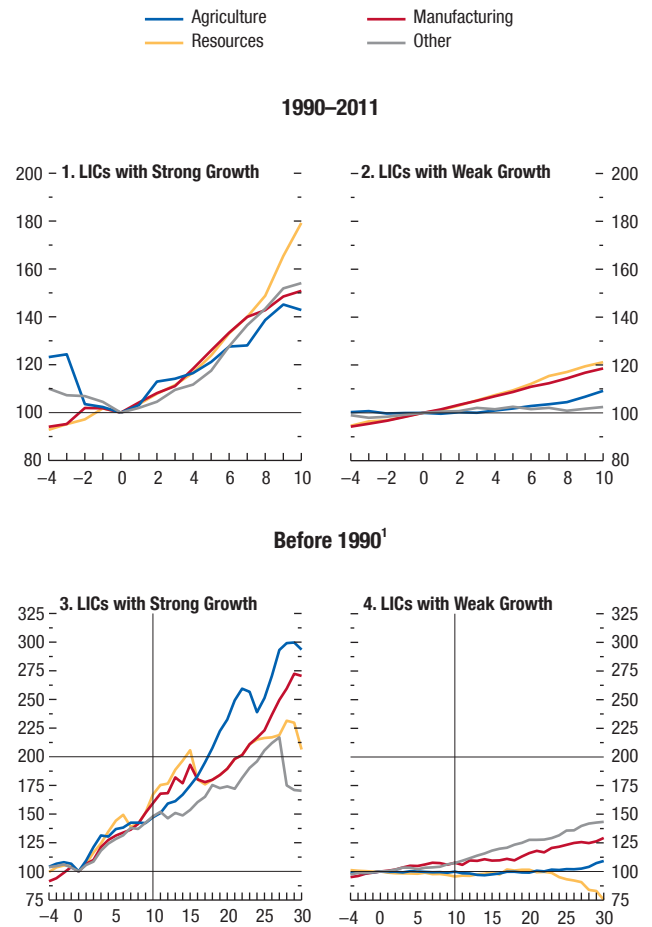

This section draws on the growth and development literature to address two key questions about the nature of LIC growth takeoffs. First, is takeoff associated with strong investment growth? The idea that investment is crucial to fostering growth in developing economies has a long history.¹¹ Second, is the growth strategy likely to endure? Even if investment were strong, growth could still fizzle if investment is not financed by sustainable means—giving rise to macroeconomic imbalances—or if it is not productive. Thus, to catalyze a takeoff and sustain it, strong investment

¹¹See, for instance, Rostow (1956) and Rosenstein-Rodan (1943), among others.

Figure 4.5. Economic Structure and Real Output per Capita after Takeoff in Low-Income Countries

(Median economy; normalized to 100 at $t = 0$, the year before the start of a strong or weak growth episode; years on x-axis)

Among the current generation of dynamic low-income countries (LICs) resource-rich LICs have typically grown faster than others. For the previous generation, although resource-rich economies were also among the strongest performers during the first 10 years after takeoff, they were eventually overtaken by other LICs. Among the weak performers, resource-rich LICs experienced the slowest growth.

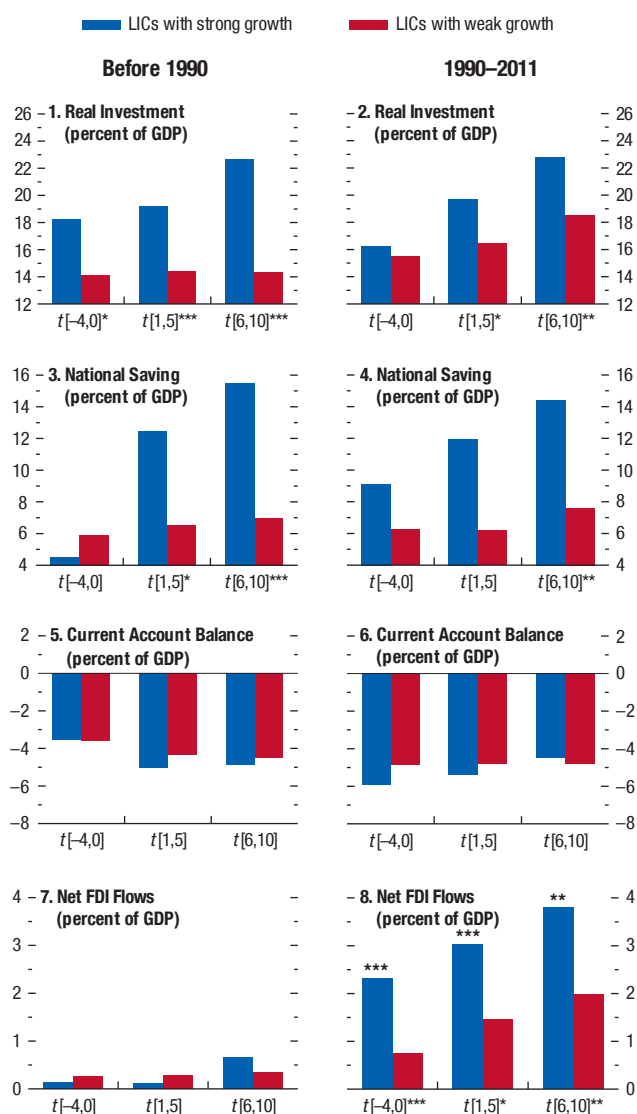

Source: IMF staff calculations.

Note: Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data.

¹The vertical line indicates the 10-year horizon.

Figure 4.6. Investment and Financing in Low-Income Countries
(Median economy; $t = 1$ in the first year of a strong or weak growth episode)

Dynamic low-income countries (LICs) from both generations tended to experience sharp increases in investment and saving rates during and after takeoffs. However, the current generation of dynamic LICs has tended to finance its current account deficits with a significantly higher share of foreign direct investment (FDI) flows than the weaker LICs and the previous generation of dynamic LICs.

Sources: IMF, Balance of Payments Statistics database; IMF, World Economic Outlook database (October 2012); Penn World Table 7.1; World Bank, World Development Indicators database (2012); and IMF staff calculations.
Note: Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data. *, **, and *** denote statistically significant difference in distributions (based on the Kolmogorov-Smirnov test) at the 10 percent, 5 percent, and 1 percent levels, respectively. Significance tests on the x-axis are for the difference in the distributions between the groups of strong and weak growth. Significance tests on the blue bars are for the difference in the distributions across 1990–2011 and before 1990 (not shown for red bars). A constant composition sample underlies each of the panels to ensure comparability within the group of strong and weak growth episodes across time for that panel.

growth should be supported by policies that do not induce macroeconomic vulnerability and by reforms and institutions that foster productivity and competitiveness.¹² Against this premise, this section documents the differences in economic conditions in recent LIC growth takeoffs compared with those that occurred prior to the 1990s. However, all stylized facts are based on correlations and should be interpreted as associations with takeoffs rather than drivers of takeoffs.

Although both the current and previous generation of takeoffs coincided with strong investment growth, they differed significantly in how the saving-investment gaps were financed. Takeoffs in both generations were correlated with higher levels of investment and national saving rates compared with LICs that could not launch a growth takeoff (Figure 4.6, panels 1–4). In addition, current account deficits were broadly similar in both generations (Figure 4.6, panels 5 and 6). However, a larger share of the current account deficits was financed by FDI flows for the current generation of takeoffs compared with the previous generation. FDI flows also rose sharply after takeoff for the current generation of dynamic LICs compared with both the LICs with weak growth and the previous generation of dynamic LICs (Figure 4.6, panels 7 and 8).¹³

Recent LIC takeoffs were supported by sharp declines in public and external debt levels, in part as a result of their greater reliance on FDI, as well as by policy adjustments undertaken to qualify for debt relief (Figure 4.7, panels 1–4). Among the current-generation dynamic LICs, within 10 years after takeoff public debt decreased from more than 90 percent of GDP to 44 percent of GDP, and external debt fell from more than 70 percent of GDP to about 44 percent. Even if economies that received debt relief are excluded from the sample, the pattern of lower external and public debt within 10 years of takeoff still holds.¹⁴

More reliance on FDI and greater macroeconomic policy discipline have fostered similarly strong growth but lower inflation after takeoff relative to dynamic LICs in the previous generation (Figure 4.7, panels 5

¹²See Commission on Growth and Development (2008), Spence (2011), Lin (2012), and Rodrik (2003).

¹³The remarkable increase in FDI inflows to LICs has also been noted by others (Dabla-Norris and others, 2010). However, as shown below, for the manufacturing-oriented LICs, although FDI levels for the current generation exceeded those in previous generations, they did not increase sharply following takeoff. The share of foreign aid in GDP was also higher for the current generation of dynamic LICs than for the previous generation.

¹⁴See Appendix 4.2.

and 6). For the latter, public and external debt stood at 40 and 33 percent of GDP, respectively, before takeoff, but more than doubled within 10 to 20 years after takeoff, and inflation tended to increase as well.

There is no compelling evidence that recent takeoffs are accompanied by rising financial imbalances. The ratio of credit to GDP tended to increase gradually in recent takeoffs, corroborating the symbiotic relationship between financial intermediation and growth (Figure 4.7, panels 7 and 8). Still, credit-to-GDP ratios in current-generation dynamic LICs were lower than in LICs with weaker growth and in LICs that took off in the previous generation.¹⁵

Competitiveness and export growth are important for LIC takeoffs. Both today and in the previous generation, LICs with takeoffs experienced stronger export growth than LICs with weaker growth (Figure 4.8, panels 1 and 2). Today's LIC takeoffs tended to have more geographically diversified exports, which may be one reason they were able to sustain strong export growth—along with the fast growth in EMDEs such as China and India—despite anemic growth in advanced economies (Figure 4.8, panels 3 and 4).¹⁶ However, greater trade exposure to other EMDEs also implies greater exposure to risks to growth in the latter and the related risks to commodity prices.

Related to the above, export structures were also more diversified in the dynamic LICs of both generations than in those with weak growth, but diversification reversed in the 10 years after takeoff for the current generation (Figure 4.8, panels 5 and 6). The greater concentration of exports after takeoff is partly related to increased specialization in commodity-related activity in LICs that discover natural resources. Given the potential risks from such product concentration, including increased exposure to adverse external shocks and limited scope for quality upgrading, continued economic and export diversification will be needed to improve the resilience of today's LIC takeoffs.¹⁷

¹⁵Owing to data constraints, we were unable to assess other dimensions of financial stability related to prudential supervision and regulation or the use of macroprudential policies.

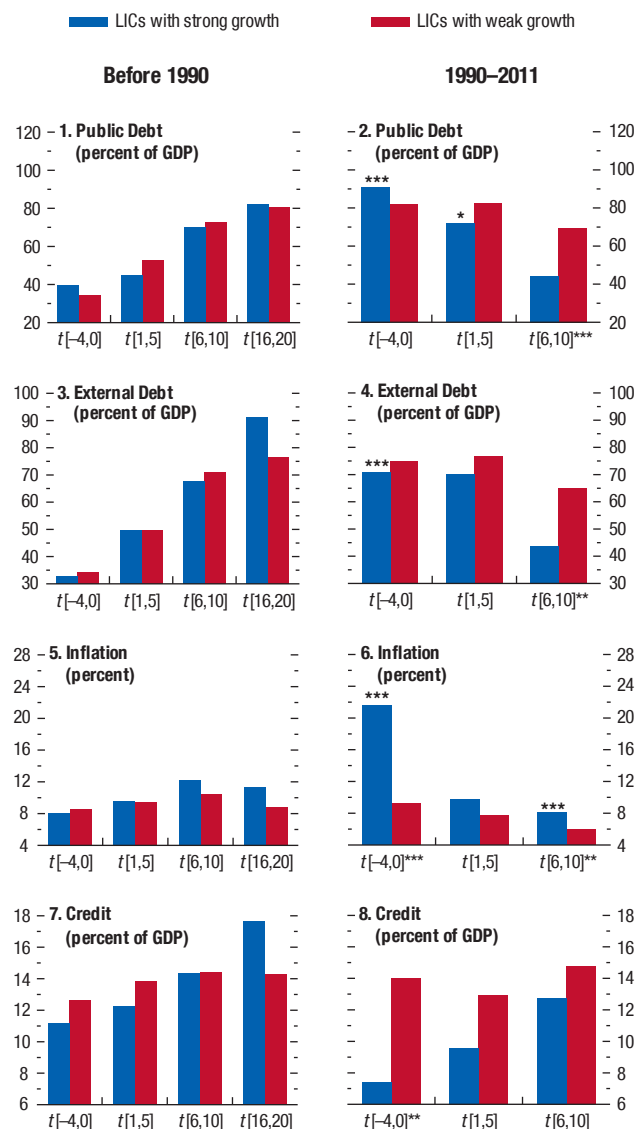

¹⁶Dabla-Norris, Espinoza, and Jahan (2012) find a sharp increase in LIC exports to emerging markets during the past three decades. They find that China and India have become significant destinations for LIC exports from all regions, whereas other emerging market economies, such as Brazil, Mexico, Russia, Saudi Arabia, South Africa, and Turkey, account for a large share of regional LIC exports.

¹⁷See, for example, Hausmann, Rodriguez, and Wagner (2006) and Papageorgiou and Spatafora (2012) for the benefits of economic diversification.

Figure 4.7. Macroeconomic Conditions in Low-Income Countries

(Median economy; $t = 1$ in the first year of a strong or weak growth episode)

Recent takeoffs were characterized by sharp reductions in public and external debt levels and inflation. In contrast, previous-generation takeoffs were characterized by generally worsening macroeconomic conditions.

Note: LICs = low-income countries. Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data. *, **, and *** denote statistically significant difference in distributions (based on the Kolmogorov-Smirnov test) at the 10 percent, 5 percent, and 1 percent levels, respectively. Significance tests on the x-axis are for the difference in the distributions between the groups of strong and weak growth. Significance tests on the blue bars are for the difference in the distributions across 1990–2011 and before 1990 (not shown for red bars). A constant composition sample underlies each of the panels to ensure comparability within the group of strong and weak growth episodes across time for that panel.

Figure 4.8. External Competitiveness, Export Growth, and Diversification in Low-Income Countries
(Median economy; $t = 1$ in the first year of a strong or weak growth episode)

In the current and previous generations of takeoffs, dynamic low-income countries (LICs) experienced stronger export growth than weakly performing LICs. Today's dynamic LICs tended to have deeper trade linkages with emerging market and developing economies

(EMDEs) and took off with more diversified exports, although diversification tended to reverse later. Today's dynamic LICs also have more competitive real exchange rates and a greater accumulation of foreign reserves.

Sources: IMF, Direction of Trade Statistics database; IMF, World Economic Outlook database (October 2012); Lane and Milesi-Ferretti (2007) updated to 2011; Papageorgiou and Spatafora (2012); Penn World Table 7.1; World Bank, World Development Indicators database (2012); and IMF staff calculations.

Note: Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data. *, **, and *** denote statistically significant difference in distributions (based on the Kolmogorov-Smirnov test) at the 10 percent, 5 percent, and 1 percent levels, respectively. Significance tests on the x-axis are for the difference in the distributions between the groups of strong and weak growth. Significance tests on the blue bars are for the difference in the distributions across 1990-2011 and before 1990 (not shown for red bars). A constant composition sample underlies each of the panels to ensure comparability within the group of strong and weak growth episodes across time for that panel.

¹The real exchange rate change is the percent change in the five-year average real exchange rate versus the United States over a five-year period.

²The real exchange rate deviation is the residual from a linear regression of the log real exchange rate versus the United States on the productivity differential of a country and the United States, as proxied by the income per capita differential.

The real exchange rate also seemed to help boost export performance for recent LIC takeoffs. Their real exchange rates versus the U.S. dollar typically depreciated during the five-year periods before and at the start of a takeoff, but there was appreciation pressure during the 6 to 10 years after takeoff (Figure 4.8, panels 7 and 8).¹⁸ However, the real exchange rate was typically some 25 to 30 percent weaker than its productivity-adjusted long-term level (Figure 4.8, panels 9 and 10), implying that these dynamic LICs were able to maintain price competitiveness.¹⁹ A greater accumulation of foreign reserves (Figure 4.8, panels 11 and 12) may have helped in this regard. For takeoffs before 1990, the behavior of the real exchange rate was not that different during the periods before and after takeoff, but it was as much as 10 to 15 percent stronger than its productivity-adjusted long-term level until five years after takeoff. This may have been associated with weaker macroeconomic conditions combined with exchange rate pegs.²⁰

LIC takeoffs tend to be complemented by improvements in the business climate and with productivity growth, but the record for the recent generation of takeoffs is much stronger than for the previous generation. Dynamic LICs in both generations tend to have smaller governments, lower regulatory barriers (proxied by the level of regulation in business, labor, and credit markets), better infrastructure, and higher human capital levels (proxied by the number of years of schooling) than LICs with weaker growth (Figure 4.9, panels 1–8). For recent takeoffs, the size of government and the level of regulatory barriers continued to decline after takeoff, and infrastructure and education continued to improve, whereas with the exception

of education, these conditions remained the same or deteriorated for the previous generation.²¹

Turning to the role of social and political institutions in underpinning growth takeoffs, the findings suggest that today's dynamic LICs performed better on these institutional measures compared with both LICs with weak growth and dynamic LICs before the 1990s. The recent literature underscores the central role of economic and political institutions in determining why some economies are able to escape poverty and sustain strong growth, whereas others are not.²² We analyze the evolution of economic and political inclusiveness, as proxied by the degree of income inequality and the degree of control over the executive, respectively (Figure 4.9, panels 9–12). Recent takeoffs display less income inequality, whereas income inequality was typically high in the previous generation of takeoffs. Political institutions are also stronger in the current generation of takeoffs—possibly reflecting the end of conflicts or greater democratization in many dynamic LICs in recent years.

Although the nature of takeoffs is broadly similar for dynamic LICs regardless of their economic structure, a few differences emerge in patterns of investment and its financing (Figure 4.10).²³ For resource-rich dynamic LICs, investment rates increased sharply around the time of takeoff for both generations (Figure 4.10, panels 1 and 2). Although saving rates rose as well, they fell short of investment rates, resulting in current account deficits for both generations (Figure 4.10, panels 3 and 4). This deficit was somewhat larger for the current generation, but it was more than fully offset by net FDI inflows (Figure 4.10, panels 5 and 6). FDI flows accounted for less than 50 percent of the current account deficit after takeoff for the previous generation. The current generation also received a sizably higher share of foreign aid (Figure 4.10, panels 7 and 8). Thus, these LICs were able to resist building

¹⁸The real effective exchange rate is not shown because fewer LICs have these data. For those that do, the observed pattern is similar to that based on the real exchange rate versus the U.S. dollar.

¹⁹The measure for the long-term real exchange rate level follows Rodrik (2008). It involves the regression of an economy's real exchange rate—measured by the price level relative to that of the United States—on its real GDP per capita relative to that of the United States. The predicted value of the real exchange rate from this regression provides the long-term level of the real exchange rate, whereas the difference between the predicted and actual real exchange rate is the degree of overvaluation. See also Johnson, Ostry, and Subramanian (2007).

²⁰We also find a much lower share of fixed and hard pegs among dynamic LICs of the current generation relative both to LICs with weak growth and to dynamic LICs of the previous generation. For the latter it is possible that fixed exchange rate regimes, combined with other macroeconomic vulnerabilities, including rising inflation pressure, resulted in the observed overvaluation.

²¹Aiyar and others (2013) discuss the positive association between deterioration in these measures and economic deceleration in middle-income countries, suggesting that productivity-enhancing structural reforms are not just important for LICs.

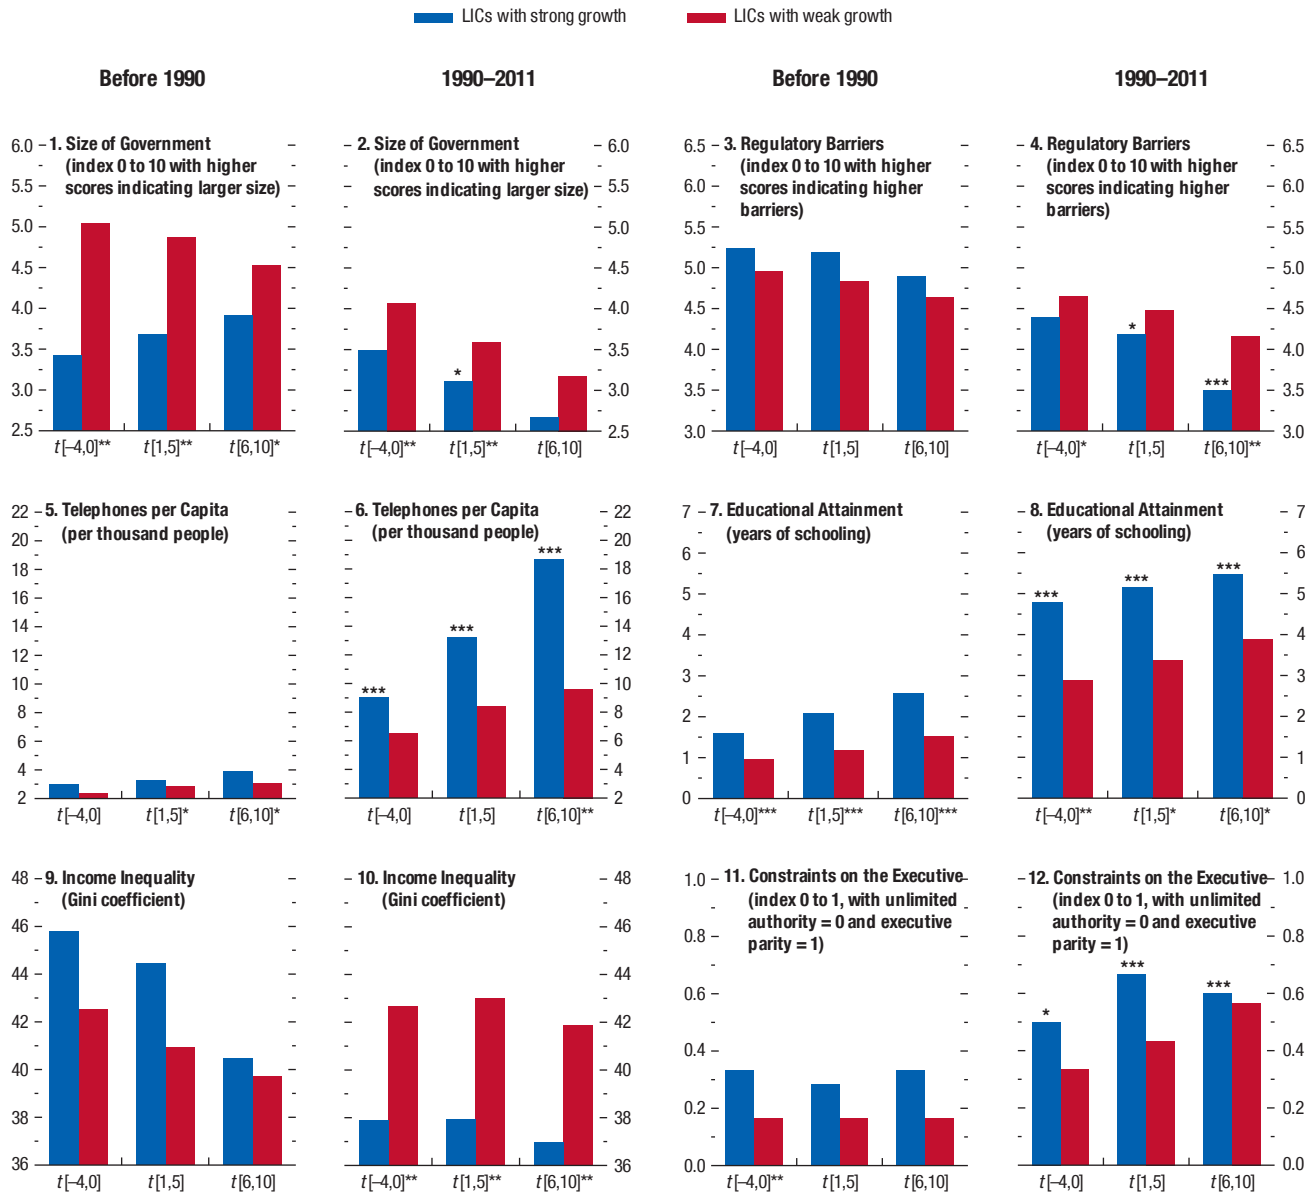

²²See Acemoglu and Robinson (2012) and Johnson, Ostry, and Subramanian (2007) on the role of political institutions. See Berg, Ostry, and Zettelmeyer (2012); Hausmann, Pritchett, and Rodrik (2005); and Abiad and others (2012) on economic institutions as proxied by income inequality. Although not shown here, we found that recent takeoffs were positively correlated with greater life expectancy as well.

²³It was not possible to conduct tests for statistical significance across the groups owing to the small number of countries in each group.

Figure 4.9. Structural Reforms, Infrastructure, and Political Conditions in Low-Income Countries
(Median economy; $t = 1$ in the first year of a strong or weak growth episode)

Today's dynamic low-income countries (LICs) tend to have smaller governments, lower regulatory barriers, and better infrastructure than their weaker counterparts from the current generation and dynamic LICs of previous generations. In addition, growth takeoffs

tended to occur in economies with higher human capital levels and, for the current generation, more equal income distributions. The current generation of LICs also tends to have better checks and balances on the executive branch of the government.

Note: Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data. *, **, and *** denote statistically significant difference in distributions (based on the Kolmogorov-Smirnov test) at the 10 percent, 5 percent, and 1 percent levels, respectively. Significance tests on the x-axis are for the difference in the distributions between the groups of strong and weak growth. Significance tests on the blue bars are for the difference in the distributions across 1990–2011 and before 1990 (not shown for red bars). A constant composition sample underlies each of the panels to ensure comparability within the group of strong and weak growth episodes across time for that panel.

Figure 4.10. Investment and Financing across the Spectrum of Today's Dynamic Low-Income Countries
(Median economy; $t = 1$ in the first year of a strong growth episode)

Investment rates were relatively high for both generations of dynamic low-income countries (LICs). However, external financing of this investment differed across groups. In the current generation, resource-oriented economies benefited most from foreign direct investment (FDI), while agriculture- and other-oriented economies benefited most from

aid. Partly because of shifts in external financing, external debt eventually fell for all groups of today's dynamic LICs. Moreover, today's manufacturing- and resource-oriented economies helped to fuel their growth by reducing regulatory barriers while strengthening political institutions. At the same time, educational attainment improved for all groups.

Sources: Barro and Lee (2010); Gwartney, Lawson, and Hall (2012); IMF, Balance of Payments Statistics database; IMF, International Financial Statistics database; IMF, World Economic Outlook database (October 2012); Lane and Milesi-Ferretti (2007) updated to 2011; Penn World Table 7.1; Political Regime Characteristics and Transitions database (2011); World Bank, World Development Indicators database; and IMF staff calculations.

Note: Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for the definition of weak growth episodes (takeoffs). See Appendix 4.1 for the definition of conflict and the source of the conflict data. A constant composition sample underlies each of the panels to ensure comparability within the group of strong and weak growth episodes across time for that panel. Bars are plotted only if there are at least three takeoffs.

up external debt after takeoff (Figure 4.10, panels 9 and 10). Resource-rich dynamic LICs from the current generation also outperformed their resource-rich peers of the previous generation in terms of stronger human capital levels, lower regulatory barriers, and stronger political institutions (Figure 4.10, panels 11–16). Such reforms, if sustained, will help these LICs engineer more broad-based growth over time (see the example of Indonesia below).

Takeoffs in today's manufacturing-oriented dynamic LICs were associated with lower investment than in the past (see Figure 4.10). However, this did not compromise their growth rates, GDP per capita increased 50 percent after 10 years for both generations (see Figure 4.5). This suggests that the current generation likely enjoyed greater productivity gains. Indeed, proxies for productivity-inducing structural conditions and institutions were much stronger for the current generation of LIC compared with their peers of the past. However, these LICs may still need to raise the rate of productive investment over time: manufacturing-oriented dynamic LICs in the past had stronger investment rates than did their resource-rich counterparts and eventually had stronger output per capita gains. Finally, the current generation of manufacturing-oriented LICs also had lower current account deficits than did the previous generation, and their net FDI and aid inflows were marginally higher. Some manufacturing-oriented dynamic LICs have recently experienced sharp increases in FDI, intended to raise investment and spur export growth and diversification (see the example of Cambodia below).

These stylized facts inspire more confidence in the strength of recent LIC growth takeoffs compared with those in the past. The correlations cannot answer whether there are one or more key drivers of these takeoffs, and in all likelihood the recent takeoffs were the result of a combination of several factors and their interplay with global conditions. Moreover, the policy improvements thus far may not be enough for sustained improvements in growth and income convergence. That said, the overall picture is promising. The strong investment-oriented and externally oriented growth in recent takeoffs relied less on foreign borrowing, which likely gave dynamic LICs more room for policy maneuver. Growth was also helped by a broad range of productivity-enhancing structural reforms, although further export diversification will be essential to improve their economic resilience. Finally, recent

takeoffs have also occurred under more inclusive institutions. Many of these indicators are regarded as key determinants of sustained growth and bode well for today's dynamic LICs, particularly if they can maintain their policy momentum.²⁴

Putting It All Together

To assess which conditions and policies are most strongly associated with growth takeoffs, the conditional probability of an LIC growth takeoff is estimated at an annual frequency. A logistic regression (logit) model allows the analysis to jointly consider a number of indicators identified as important in the stylized facts, depending on their data availability over the sample period. However, as in most statistical investigations, all estimated relationships should be interpreted solely as associational, rather than causal. Moreover, given the limited availability of data for many variables and the relative rarity of a takeoff, the model's results should be taken with a grain of salt.²⁵

The overall picture suggests that a country's chances of a new growth takeoff are related both to the global economic environment and to the initial levels and changes in the LIC's domestic macroeconomic conditions and structural characteristics (Table 4.4). Some of these relationships have changed since 1990 (highlighted in bold in the table). In particular, the following have become more important: a more competitive exchange rate, deeper export links with other EMDEs, higher human capital levels, initial levels of income per capita, and overall economic size. Indeed, as global trade and competition increase, greater external competitiveness, export diversification, and productivity improvements may raise LICs' chances of takeoff relatively more than when the global economy is less integrated.

The baseline results suggest that the chances of takeoff more than tripled during the 2000s compared with the period before 1990 (Figure 4.11). The predicted

²⁴See Berg, Ostry, and Zettelmeyer (2012); Hausmann, Pritchett, and Rodrik (2005); Jones and Olken (2008); and Abiad and others (2012).

²⁵A number of variables that stood out as significantly different for the current generation of takeoffs could not be incorporated into the logit model because of limited data coverage. These include net FDI flows, external debt, foreign reserves, and income inequality, among others. For the robustness of the findings to the rare-events problem and alternative definitions of low income, criteria for identifying takeoff, and estimation methods, see Appendix 4.3.

annual probability of a new takeoff in any given year increased from less than 1 percent before 1990 to close to 3 percent during the 2000s. Improved structural conditions (particularly, more years of schooling) contributed most to this increase. Better macroeconomic conditions (higher investment growth, falling debt) are the next most important. Finally, stronger global conditions and more outward-oriented policies (a more competitive real exchange rate, more exports to EMDEs) equally boosted the chance of a new takeoff. Higher initial income per capita in the 2000s lowered the chance of a takeoff, reflecting convergence, whereas larger economic size raised it, suggesting gains from economies of scale. However, as noted, the results should be treated with caution because these are only associations and because data issues preclude a deeper analysis of some channels.

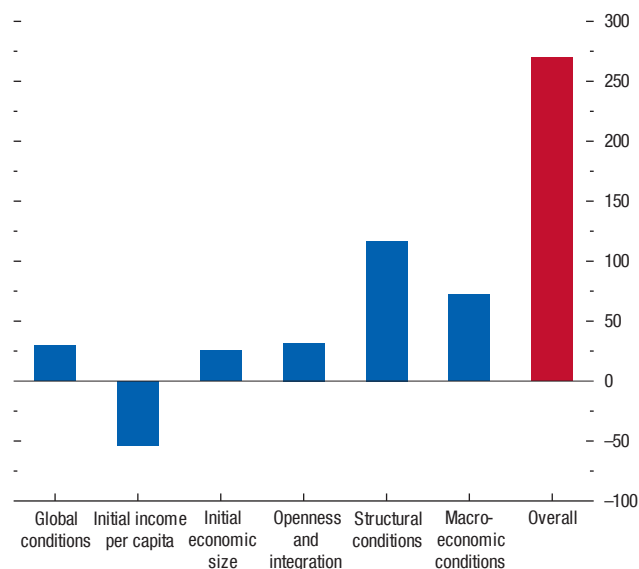

Lessons from History

This section looks at five individual experiences with growth takeoffs to provide more details on the specific policies and conditions that affected these countries' macroeconomic outcomes after takeoff. The cases include two economies that pursued industrial development with very different growth strategies (Brazil and Korea, 1960–80),²⁶ a resource-rich economy that diversified into manufacturing (Indonesia since the mid-1960s), an economy that is shifting into commodities (Mozambique since the mid-1990s), and an economy driven by manufacturing activity (Cambodia since the mid-1990s). Rather than a detailed discussion of the country experiences, which is already available for some of these cases in the development literature (see the references for each case study), the focus here is on drawing out differences in these countries' growth and investment strategies, the financing of their saving-investment gaps, and policy measures that affected productivity and competitiveness.

²⁶Note that Brazil and Korea were not LICs at the time of their takeoffs, as determined by the chapter's baseline definition of a time-varying low-income threshold. However, their initial income levels were low in absolute terms, and their experiences portray efforts in structural transformation and development.

Figure 4.11. Contributors to the Changing Likelihood of a Growth Takeoff in Low-Income Countries
(Percent change in odds ratio; 2000s versus before 1990)

The predicted annual chance of a strong growth takeoff for an average low-income country was larger in the 2000s than it was before 1990. More favorable global conditions, greater economic size, a larger share of exports going to emerging market and developing economies, a more competitive real exchange rate, more years of schooling, higher investment, lower inflation, and lower public debt all contributed to this rise; higher initial income per capita lowered the chances.

Source: IMF staff calculations.
Note: The odds ratio is the probability of starting a takeoff divided by the probability of not starting one. The estimated contribution of the variables to the percent change in the predicted odds ratio is based on the logistic regression coefficient estimates in Table 4.4, for the full sample. The variable groups shown correspond to those in Table 4.4. The average values of the variables over either the period before 1990 or 2000–11 are used to calculate the predicted odds ratio. The associated predicted probabilities at these average values are 0.8 percent for the subsample before 1990 and 2.8 percent for the 2000–11 subsample. To calculate the overall change, the product of the contributions is used. See Appendix 4.3 for additional details on the model specification and estimation.

Note: The dependent variable is a dummy variable for the start of a new growth takeoff. Indicators (variables) are defined in Appendix 4.1. Heteroscedasticity and autocorrelation within country robust standard errors are in parentheses under the logistic (logit) regression coefficient estimates. *, **, and *** denote significance at the 10 percent, 5 percent, and 1 percent levels, respectively. Statistically significantly different coefficient estimates across the subsamples before 1990 and for 1990–2011 are shown in bold (at the 10 percent level or lower). The average marginal effects by variable on the chances of a new growth takeoff are shown in the column next to the corresponding sample's logit coefficients. The marginal effect shows the average impact of a one-unit change in the explanatory variable on the probability of a growth takeoff (scaled to range from zero to 100).

¹EMDEs = emerging market and developing economies.²AUC = area under the receiver operating characteristic curve.

Brazil and Korea, 1960–80: Strong Takeoffs but Diverging Trajectories²⁷

These two experiences emphasize the importance of mobilizing sustainable finances for an investment-driven growth strategy. Although both these economies focused on industrialization, Brazil increasingly relied on external debt to finance its saving-investment gap, and the situation was exacerbated by growing public debt. Korea started out with a much worse current account position than Brazil, but strengthened its external balances with greater fiscal discipline, higher domestic saving rates, and strong export growth.

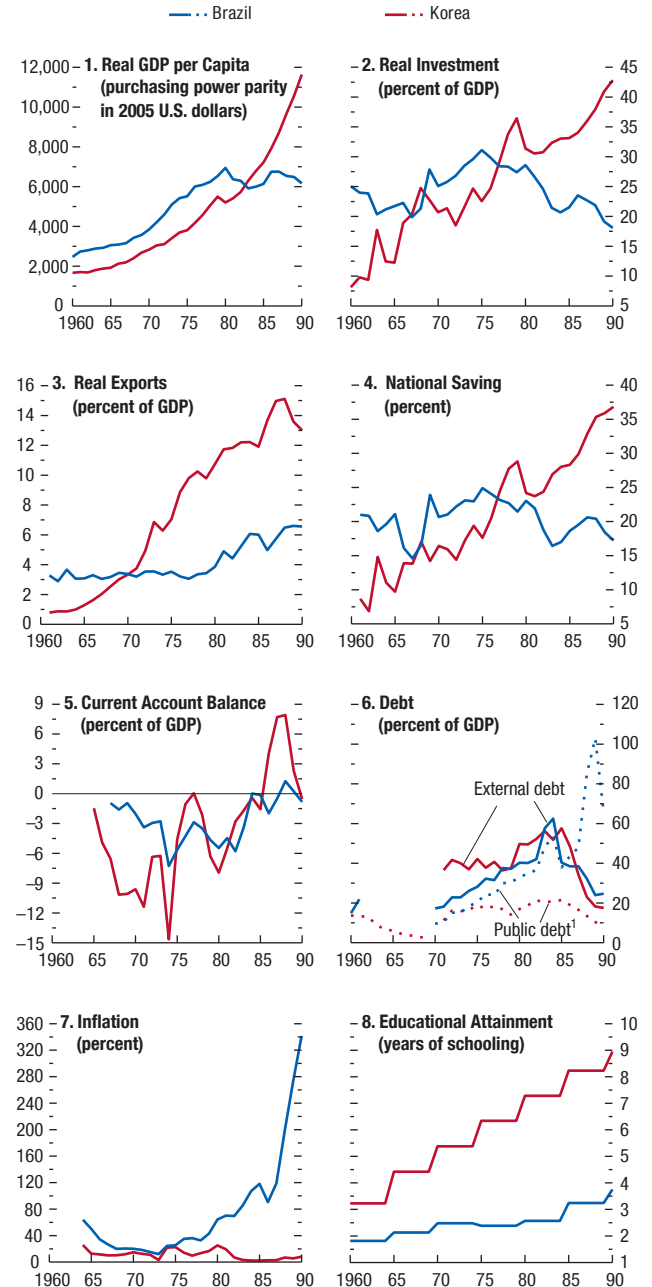

Both Brazil and Korea experienced strong growth between 1960 and 1980, but their post-1980 experiences were diametrically opposite (Figure 4.12, panel 1). In Brazil, output per capita stagnated for more than two decades after a debt crisis in the early 1980s. In Korea, after a recession in 1980, the economy regained momentum.

Although both economies pursued industrial development policies, they had markedly different growth strategies. Brazil's growth model was oriented inward, with production geared toward its large domestic market. Import substitution—which discouraged imports and subsidized domestic producers—was the cornerstone of the strategy. Growth was driven mainly by domestic demand, and export growth was slow (Figure 4.12, panels 2 and 3). In contrast, Korea began to shift away from import-substitution policies beginning in the 1960s and became increasingly export oriented. Initially, the government promoted labor-intensive industrial exports, but in the face of increased protectionism for labor-intensive industries in advanced economies, the focus shifted to promoting higher-value-added industries. Large-scale investment in shipbuilding, steel, and petrochemicals helped Korea become a leading producer and exporter in these sectors.

The ways in which Brazil and Korea financed investment, particularly after the first oil price shock in the early 1970s, also help explain the differences in their macroeconomic outcomes. Although Brazil's national saving rate was high, it did not keep pace with investment. The rising current account deficit was increasingly financed by external borrowing. Public debt also rose beginning in the 1970s (Figure 4.12, panels 4–6).

Figure 4.12. Brazil's and Korea's Growth Experiences during 1960–90

These two experiences emphasize the importance of mobilizing sustainable finance for an investment-driven growth strategy. Although both economies focused on industrialization, Brazil increasingly relied on external debt to finance its saving-investment gap, and the situation was exacerbated by growing public debt. Korea started out with a much worse current account position than Brazil, but strengthened its external balances with greater fiscal discipline, higher domestic saving rates, and strong export growth.

Figure 4.13. Indonesia's Growth Experience since the 1960s

Indonesia's experience stands out not only because growth was remarkably strong over a long period, but also because the economy was able to achieve a structural shift from commodities into the manufacturing sector. The use of oil windfalls to develop infrastructure, and strengthen health and education, and the continued focus on rural development and agricultural productivity, also allowed growth to be more inclusive.

Sources: Abbas and others (2010); IMF, International Financial Statistics database; IMF, World Economic Outlook database (October 2012); Lane and Milesi-Ferretti (2007) updated to 2011; Penn World Table 7.1; Solt (2009); World Bank, World Development Indicators database (2012); and IMF staff calculations.
 Note: Indicators are defined in Appendix 4.1.
¹Income inequality data are missing from 1966 to 1969.

Overheating pressure intensified when policies to push growth were not adjusted after the first oil shock (Figure 4.12, panel 7). Debt became unsustainable after the economy was hit by the second oil price shock, combined with significantly higher world interest rates, culminating in the debt crisis. Korea also had a large current account deficit until the early 1970s, which was financed with foreign aid and external borrowing. However, the saving rate grew rapidly over time: the budget deficit stayed relatively low and the government encouraged both personal saving, through mandatory long-term saving for civil servants and other employees, and corporate saving, through a policy mandating low dividends. This helped narrow the current account deficit in the 1970s. Although it rose again after the second oil shock, it fell soon thereafter on the back of strong export growth. Fiscal discipline and strict monetary targeting helped keep inflation under control.

Policies in Korea were better aligned with maintaining external competitiveness and sustaining investment productivity, and these in turn were helped by macroeconomic policies to contain internal imbalances. The real exchange rate was maintained at a relatively depreciated level (using step devaluations within an implicit crawling peg), exporters received a variety of incentives, and labor skills in key sectors were upgraded via vocational and in-plant training. The government put a high priority on increasing overall education levels (Figure 4.12, panel 8). In the 1960s, when policy promoted labor-intensive industries, the emphasis was on general education. Later, when high-value-added industries were targeted, the emphasis was on strengthening engineering education and establishing specialized research institutes. Income inequality remained relatively low in Korea even after takeoff, whereas Brazil experienced persistently high income inequality and slow educational advancements.

Indonesia, Mid-1960s to Present: Growth with Shared Prosperity²⁸

Indonesia's experience stands out not only because growth remained remarkably strong over a long period but also because the structure of the economy successfully shifted from commodities to manufacturing (Figure 4.13). The development strategy put a priority on rural and agricultural development, and oil windfalls were used to develop infrastructure and strengthen health and

²⁸This case study draws on Temple (2003), Timmer (2007), and World Bank (2005).

education. Thus, growth was both strong and relatively inclusive.

Indonesia's takeoff started out with commodities and became more broad based over time. Growth was led by the energy sector until the early 1980s and increasingly by the manufacturing sector afterward (Figure 4.13, panels 1 and 2). In the 1960s and 1970s, a large share of the government's revenue from commodity windfall gains was directed toward public investment in rural infrastructure, agriculture, health, and education.²⁹ When the oil boom ended in the early 1980s, the government supported a shift toward manufacturing. Private investment and export growth were encouraged through industrial deregulation and through trade, capital account, and financial liberalization (Figure 4.13, panel 3). At the same time, growth in the agricultural sector was supported by efforts to improve agricultural productivity, including through the adoption of high-yield seeds and increased use of fertilizers and irrigation—so-called Green Revolution technologies. Strong growth during this period was accompanied by sharp declines in poverty levels and relatively low income inequality (Figure 4.13, panel 4).

Growth was also accompanied by macroeconomic policy discipline. The government used strict monetary targets to reduce inflation from triple digits in the mid-1960s to less than 15 percent by the end of that decade. Fiscal targets adopted in the late 1970s kept public debt relatively low (Figure 4.13, panel 5). However, strong growth and macroeconomic stability masked some latent financial and corporate sector imbalances, whereby financial deregulation in the absence of adequate prudential regulation and supervision fueled a credit boom centered in the property sector beginning in the 1980s (Figure 4.13, panel 6). The boom was financed by short-term capital flows in the context of a pegged exchange rate regime. In 1998, after the economy was hit by contagion from Thailand, Indonesia experienced a banking and balance of payments crisis. The economy rebounded again in 2000, based on stronger macroeconomic policies and structural reforms. Annual growth in per capita real GDP averaged 3¾ percent in the 2000s, and Indonesia remained resilient through the Great Recession.

²⁹The contribution of the oil boom to economic development in other sectors also reduced the risk of Dutch disease effects. Moreover, the pro-poor growth focus contrasts sharply with the behavior often associated with resource-rich economies—namely, risky investment of resource windfalls.

Mozambique, 1990s to Present: How Will History See It?³⁰

Mozambique's experience highlights the benefits of undertaking policies and measures that attract FDI to finance private investment. It also reveals the challenges arising from commodity-based growth, specifically the need for durable structural reforms that support broad-based improvements in productivity, growth, and living standards.

Peace and political stability have supported vibrant growth in Mozambique for nearly two decades. By the end of the civil war in 1992, Mozambique had endured nearly 30 years of conflict and was the second poorest country in our sample of LICs.³¹ However, the economy rebounded in 1996, and annual growth in per capita real GDP averaged 5¾ percent over the next 16 years (Figure 4.14, panel 1).

Growth was driven by a surge in investment, supported by improvements in the business climate. Investment before the takeoff largely reflected aid-financed reconstruction (Figure 4.14, panels 2 and 3). After takeoff, investment included public-private initiatives for infrastructure building to develop the resource sector. The government took several steps to make the economy more investment friendly, including establishing a one-stop investment center, improving investor property rights and contract enforcement, and providing generous tax incentives.³² Although investment declined after the completion of major infrastructure projects, growth was sustained with a commensurate rise in resource exports, particularly aluminum. Investment in the resource sector accelerated again in recent years, particularly in coal mining and

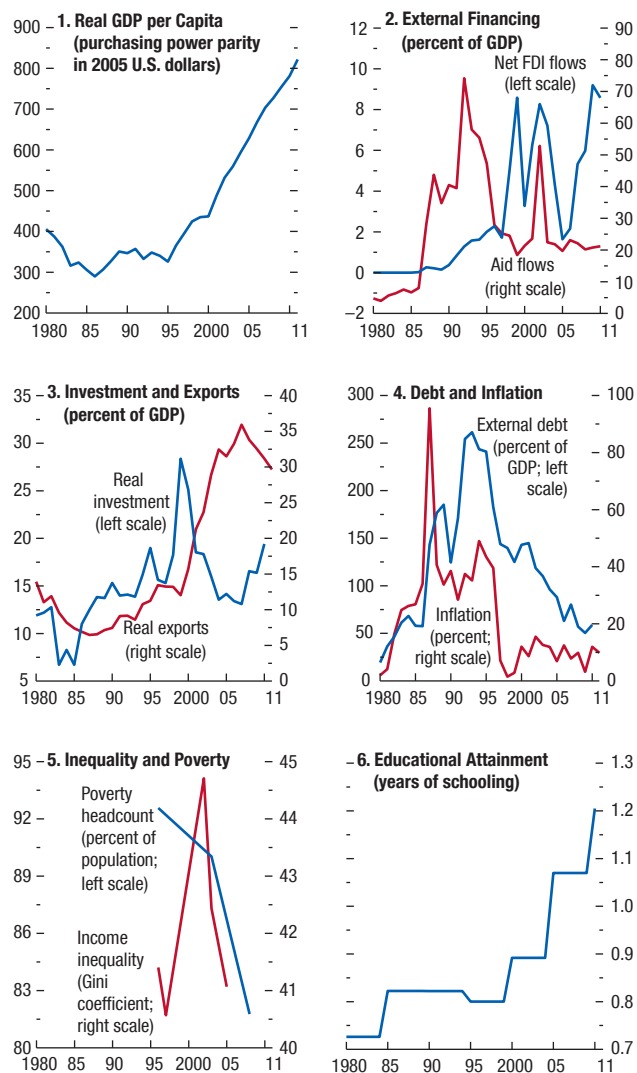

³⁰This study draws on: African Development Bank (2012); Banco Português de Investimento (2012); Batley (2005); Brück (1997, 2006); Brück, FitzGerald, and Grigsby (2000); Canning (1998); Clément and Peiris (2008); Economic Commission for Africa (2004); Hall and Young (1997); Hoeffler (2000); Lledó and Garcia-Verdu (2011); Pretorius (2000); Schwartz, Hahn, and Bannon (2004); United Nations (2012); United Nations Development Program (2011); Vitek (2009); and Wiles, Selvester, and Fidalgo (2005).

³¹Mozambique's war of independence against Portugal started in 1964 and came to an unexpected end with the military coup in Portugal in April 1974. The civil war began in 1977 and lasted until 1992.

³²Specifically, the government supported establishment of "development corridors," which created industrial clusters along major highways and connected these clusters to a port. A key project focused on processing imported bauxite into aluminum for export. Note that although we highlight the role of domestic policies, other factors also played a role in investment growth, including the country's vast natural resources, favorable global commodity prices, and continued donor support, as well as proximity to South Africa and recent alliances with other EMDEs.

Figure 4.14. Mozambique's Growth Experience since the 1990s

Mozambique's experience highlights the benefits of undertaking policies and measures that attract private investment financed by foreign direct investment (FDI). It also reveals the challenges arising from commodity-based growth, whereby lasting structural reforms will be needed for broad-based improvements in productivity, growth, and living standards.

Sources: Barro and Lee (2010); IMF, Balance of Payments Statistics database; IMF, World Economic Outlook database (October 2012); Lane and Milesi-Ferretti (2007) updated to 2011; Penn World Table 7.1; Solt (2009); World Bank, World Development Indicators database (2012); and IMF staff calculations.

Note: Indicators are defined in Appendix 4.1.

natural gas exploration (the existence of vast offshore gas fields was confirmed in 2011).

Given its own limited savings, the government sought to attract FDI to fund its public-private investment projects. Improved macroeconomic policies—relatively low inflation and reduction in fiscal deficits—helped provide a stable economic environment for such FDI (Figure 4.14, panel 4). Mozambique qualified for debt relief under the Heavily Indebted Poor Country Initiative and Multilateral Debt Relief Initiative, which freed up fiscal space for the government's contributions for the infrastructure projects.

Nonetheless, Mozambique's growth experience has been capital intensive and focused on resources. As such, its investment projects have generated employment only to a limited extent. It has also allowed only limited fiscal gains, given the tax exemptions for these projects. Furthermore, there have been only modest declines in poverty and income inequality, and slow improvement in health and education, despite donor support (Figure 4.14, panels 5 and 6). The country ranks among the poorest performers in the United Nations Development Program's *Human Development Report*. Moreover, although the FDI- and aid-financed growth strategy has reduced vulnerabilities related to external borrowing, it has raised the risks of Dutch disease effects that will need to be addressed.

Thus, the economy faces an unfinished policy agenda. In this context, the experience of Indonesia in the 1960s and 1970s in reorienting investment toward rural and agricultural development is illuminating. Key policy priorities for Mozambique include developing transport and energy infrastructures, continuing to enhance human capital, ensuring access to financing more broadly to attract domestic private investment, and expanding the use of agricultural land to enhance agricultural productivity.

Cambodia, 1990s to Present: Remarkable Strides, but Far to Go³³

Cambodia's experience underscores the importance of peace and stability as well as that of recent government efforts toward investment and development. It also illustrates the benefits of tapping into a vibrant regional production chain. However, Cambodia still needs to make

³³This study draws on Coe (2006), IMF (2011, 2012a, 2013, forthcoming), and Rungcharoenkitkul (2012).

significant improvements to its infrastructure and business climate to attract private investment and further diversify its economy.

Real GDP per capita gained momentum in the mid-1990s when reconstruction, macroeconomic adjustments, and structural reform bore fruit after years of conflict and political tension. Rapid growth has continued for nearly two decades, and output per capita has grown at an average annual rate of 6 percent over the past decade (Figure 4.15, panel 1). This suggests that Cambodia's takeoff is more than a postconflict recovery story.

Growth has been supported by a steady rise in investment related to the export-oriented textile industry, although more recently also to investment in infrastructure (Figure 4.15, panels 2 and 3). The growth takeoff was catalyzed by Cambodia's preferential access to the United States under the Multi-Fiber Arrangement (MFA).³⁴ Investment growth decelerated in the early 2000s in part because of concerns about a burdensome regulatory environment, but it picked up again recently, after a concerted government effort to improve the business climate.³⁵ Recent public-private initiatives have focused on power generation and rural development. Rice exports have increased sharply since 2010, largely as the result of measures to boost yields, storage capacity, and trade.

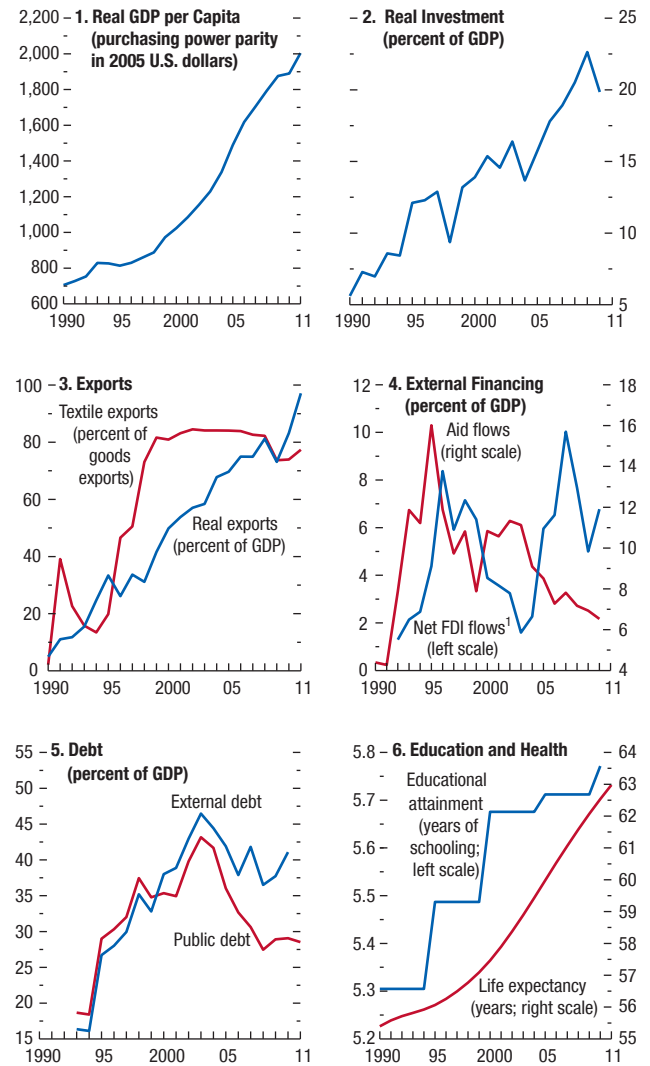

Cambodia has relied heavily on FDI to finance its saving-investment gap (Figure 4.15, panel 4). Recent FDI flows have been harnessed into public-private initiatives to improve power generation. The economy's relatively open trade and investment regimes, combined with Cambodia's proximity to some of the most dynamic economies in the world, have also attracted FDI in the manufacturing sector recently. In fact, there have been promising signs of diversification in the manufacturing sector, particularly through outsourcing efforts by multinational companies that are responding to rising wages elsewhere in Asia, and these will likely increase with improved power generation. Thus far, the textile sector continues to dominate the economy—accounting for three-quarters of total exports of goods—followed by tourism and agricultural products.

³⁴Although the MFA ended in 2005, Cambodia has continued to enjoy preferential access to markets in the European Union.

³⁵Cambodia's rank in the World Bank's *Doing Business* indicators moved up by eight places in 2012, to 133rd out of 185 countries, for several measures to reduce the regulatory burden and improve the business climate. The government also strengthened enforcement of the anticorruption law in 2011.

Figure 4.15. Cambodia's Growth Experience since the 1990s

Cambodia's experience underscores the importance of peace and stability and recent government efforts for investment and development. It also illustrates the benefits of proximity to dynamic economies and joining the regional production chain. However, efforts are needed to improve the economy's infrastructure and business climate to attract private investment and accomplish further diversification.

Sources: Abbas and others (2010); Barro and Lee (2010); IMF, Balance of Payments Statistics database; IMF, World Economic Outlook database (October 2012); Lane and Milesi-Ferretti (2007) updated to 2011; Penn World Table 7.1; UN Comtrade Statistics; World Bank, World Development Indicators database (2012); and IMF staff calculations.

Note: Indicators are defined in Appendix 4.1.

¹FDI = foreign direct investment.

Sustaining strong growth in Cambodia will require further economic diversification and strengthened macroeconomic policies. Removing infrastructure bottlenecks and improving the business climate will remain critical for attracting private investment and for further diversification. Financial intermediation must continue to deepen, and financial stability must be maintained through strong prudential supervision and regulation—the credit-to-GDP ratio has quadrupled to 35 percent in less than 10 years and continues to rise unabated. Improved public debt management will lower risks arising from the potentially large contingent fiscal liabilities inherent in substantial public-private initiatives. Mobilizing fiscal revenue will help build fiscal buffers to meet the country's development needs, including human capital development through improved health and education (Figure 4.15, panels 5 and 6).

Takeaways from the Case Studies

The case studies echo the development literature in emphasizing that growth takeoffs are feasible under a variety of development strategies. Growth was strong in all five of these economies despite their different economic structures and strategies. Cambodia, Indonesia, Korea, and Mozambique took the standard route of promoting growth through investment and exports; in Brazil, investment was geared toward the domestic market. The degree of government involvement also varied among these countries. In Mozambique and Cambodia in the 1990s, the government focused on maintaining political stability in the postwar era—the key prerequisite for growth—and developing an investment-friendly environment. There was much heavier public sector involvement in Brazil and Korea in the 1960s, with varying macroeconomic effects.

However, a key lesson from these countries' experiences is that sustaining strong growth requires continued effort to reduce external and internal imbalances. For all five economies, the growth takeoff was accompanied by some narrowing of fiscal and external current account deficits, but not all were able to sustain this momentum. Where imbalances grew or where growth was excessively reliant on foreign borrowing, the takeoffs ended disruptively or were interrupted even after decades of strong growth (Brazil in 1982, Indonesia in 1997). These experiences suggest that today's dynamic LICs, now only 9 to 12 years into

their takeoffs, should avoid financing investment by excessive debt. Further reductions in their debt levels—which are still relatively high at more than 40 percent of GDP—are needed to build the fiscal space required for higher public investment.

A second lesson is that structural reforms can be instrumental in raising productivity and ensuring broad-based growth. In Korea, labor training in the export-oriented sectors helped sustain growth by moving the manufacturing sector up the value chain. In both Korea and Indonesia in the 1960s, measures were taken to upgrade agricultural productivity, infrastructure, and human capital, and these raised living standards on a broad scale. In contrast, growth from infrastructure projects and import substitution in Brazil in the 1960s did not alleviate income inequality. Similarly, the capital-intensive growth under way in Mozambique, with limited employment generation, may increase social vulnerabilities unless emphasis continues on improving productivity, education, and health. In addition, although Mozambique's FDI-financed growth strategy produces less debt, it could produce Dutch disease challenges as the economy broadens its growth strategy.

Finally, these countries' experiences demonstrate that policies need to adjust to changing global conditions. Strong global growth, low interest rates, and terms-of-trade gains or preferential access to larger markets benefited all five economies at different times. Indonesia's timely shift from natural resources helped it maintain strong growth even after the end of the oil price boom in the 1980s and underscores the significance of further economic diversification for many of today's dynamic LICs. Brazil's struggle to adjust domestic demand to the oil price shocks of the 1970s exacerbated its external imbalances. The important lesson for today's LICs is to avoid procyclical policies despite the prevalence of ultralow global interest rates.

Policy Conclusions

The turn of the 21st century has brought new hope for many LICs. This chapter finds that growth in a significant number of LICs has taken off—defined as an expansion in income per capita for at least five years averaging at least 3½ percent—since the 1990s. These takeoffs have already lasted 9 to 12 years on average, and more than half of these dynamic LICs continued

to expand at strong rates through the Great Recession. Compared with major LIC growth takeoffs during the 1960s and early 1970s, the post-1990 period has seen more and longer-lasting takeoffs.

The post-1990 LIC growth takeoffs resemble those in previous decades in important ways. A striking similarity is that both recent and earlier takeoffs were based on higher investment and national saving rates and greater trade integration, which sets apart dynamic LICs of both generations from LICs that failed to take off. This is consistent with the literature, which has long emphasized the key role of capital accumulation and trade integration in economic development. Export growth rose faster in dynamic LICs than in LICs that were unable to take off, and it was higher in recent takeoffs than in earlier ones.

However, the current generation of takeoffs stands apart from those in the previous generation in two key dimensions. First, today's dynamic LICs achieved strong growth without building obvious macroeconomic imbalances. For the resource-rich dynamic LICs, this was due to a much greater reliance on FDI than in the previous generation. For the others, strong growth was achieved despite lower levels of investment than in the previous generation. The more sustainable nature of recent takeoffs is reflected in lower inflation, more competitive exchange rates, and appreciably lower public and external debt accumulation. Second, the post-1990 takeoffs were also associated with faster-paced implementation of productivity-enhancing structural reforms and institution building. These include lower regulatory burdens, stronger infrastructure, higher education levels, and greater political stability. The greater effort toward lowering macroeconomic imbalances and implementing structural reforms bodes well for the future of today's dynamic LICs and highlights priorities for LICs that have yet to jump-start growth.

Despite their achievements, today's dynamic LICs have much left to accomplish. With their per capita income level still a fraction of that in advanced economies, they face a long journey toward income convergence. Moreover, these economies' greater reliance on FDI flows could lead to familiar Dutch disease challenges, which would need to be addressed. A related challenge for LICs that have relied on resource-intensive growth is to diversify their economies to raise growth, employment, and living standards on a broader scale. In sum, dynamic LICs cannot afford to

lose sight of the need to sustain the pace of reforms, avoid major macroeconomic imbalances, and maintain external competitiveness.

Appendix 4.1. Data Definitions, Sources, and Country Groupings

Data Definitions and Sources

The primary data sources for this chapter are the IMF's World Economic Outlook (WEO), Penn World Table version 7.1 (PWT; Heston, Summers, and Aten, 2012), and the World Bank's World Development Indicators (WDI) databases. All the data sources used in the analysis are listed in Table 4.5. For indicators with multiple sources, the sources are listed in the order in which they are spliced (which entails extending the level of a primary series using the growth rate of a secondary series). For example, aggregate real GDP and real GDP per capita in constant 2005 purchasing-power-parity-adjusted U.S. dollars are from the PWT, and where missing, are extended with data from the WEO and WDI.

Domestic Shocks

Bank, currency, and debt crises are from Laeven and Valencia (2012). *Conflict* indicates whether a country is involved in a serious internal or external conflict in a given year in which the country's output per capita falls by more than 3 percent. This measure is derived from information on external and internal state conflicts from the Correlates of War (COW) database (The New COW War Data, 1816–2007 v. 4.0) and the measure of real output per capita detailed earlier. In the analysis, low-income country (LIC) episodes of strong or weak growth are excluded if they occur in the year after a conflict to avoid confounding a growth takeoff with a bounce back from a war.

Economic Structure

Export concentration is from Papageorgiou and Spatafora (2012) and corresponds to the Theil index on an updated version of the UN-NBER data set, which harmonizes Comtrade bilateral trade flow data at the four-digit Standard International Trade Classification (Rev. 1) level. *Exports to emerging and developing economies* are from the IMF's Direction of Trade Statistics database. It is calculated by taking the sum of the bilateral merchandise exports data across all EMDEs (see Table 4.6 for country groupings) for a given coun-

Note: EMEs = emerging market and developing economies; FDI = foreign direct investment.

try. It is expressed as a percent of nominal GDP in U.S. dollars from the WDI, extended with the WEO. *National saving* to GDP is derived as the share of real gross national product in real GDP from the WDI minus the share of private and public consumption in real GDP from the PWT. *Real exports* to GDP is real exports of goods and services as a percent of GDP, from the WDI, extended with the WEO. *Real investment* in percent of GDP is from the PWT. *Real share of manufacturing* and *real share of resources in value added* are from the WDI. Resources are calculated as the contribution of industry in value added minus the contribution of manufacturing in value added. Total value added is the sum of value added from agriculture, industry, and services. *Textile exports* as a percent

of goods exports is from the United Nations Comtrade Statistics database.

External policies

Aid flows is from the WDI and is deflated by the U.S. consumer price index to obtain *real aid flows*. The *current account balance* in percent of GDP is from the WDI, extended with the WEO. *Foreign reserves* to GDP is from the External Wealth of Nations Mark II Database (Lane and Milesi-Ferretti, 2007). *Net FDI Flows* as a percent of GDP is from the IMF Balance of Payments Statistics database (line 4500), extended with the WEO. *Trade openness* is measured as the sum of imports and exports of goods and services divided by GDP. The individual components are from the WDI, extended with the WEO.

Note: * denotes low-income countries (LICs) anytime from 1990 onward based on a time-varying threshold for low-income output per capita. The definition of LICs is given in Appendix 4.1. The sample of countries excludes economies that had an average population less than 1 million. The group of LICs also excludes China and India. + denotes countries eligible for the Heavily Indebted Poor Countries (HIPC) Initiative.

Global environment

Global growth is the world GDP growth aggregate from the WEO, weighted by purchasing-power-parity (PPP) GDP. It is then extended by the growth of the aggregate PPP GDP levels from the PWT. The *U.S. real interest rate* is the U.S. three-month treasury bill rate (secondary market, annual average) minus the realized U.S. inflation rate, expressed in annualized percent. Both the interest rate and the inflation rate are from Haver Analytics.

International relative prices

The *real exchange rate* comes from the PWT and is the price level of GDP versus that of the United States. The *real exchange rate deviation* is the residual from a linear regression of the log real exchange rate on the productivity differential of the country with the United States, as proxied by the difference in log real GDP per

capita with the United States. The *real exchange rate change* is the percent change over a five-year period in the five-year average of the real exchange rate. The *trade-weighted terms of trade* is the percent change of the terms-of-trade index constructed using the deflators of exports and imports of goods and services and the series of GDP, exports, and imports of goods and services in nominal terms—all from the WDI and WEO. In particular, the terms-of-trade index is calculated as the ratio of the export price deflator exponentiated by the share of exports in GDP to the import price deflator exponentiated by the share of imports in GDP.

Monetary and fiscal policies

Credit as a percent of GDP is from the IMF's *International Financial Statistics* publication and refers to bank credit to the private sector (line 22D). *External debt* to GDP is from the External Wealth of Nations

Mark II database (Lane and Milesi-Ferretti, 2007). *Inflation* is calculated as the log difference of the consumer price index (CPI). CPI data are from the WDI, extended with WEO data. *Public debt* is from Abbas and others (2010) taken as a ratio to GDP; the GDP data are from the WDI, extended with WEO data. The public-debt-to-GDP ratio is then extended using the change in external debt to GDP.

Structural and political conditions

Constraints on the executive is from the Political Regime Characteristics and Transitions database (2011) but rescaled to zero to 1 (from 1 to 7): unlimited authority equals zero and executive parity equals 1. *Educational attainment* is measured by years of schooling from Barro and Lee (2010). *Income inequality* is the Gini coefficient of household disposable income from Solt (2009). *Life expectancy* is from the WDI and refers to life expectancy at birth, in years. *Poverty headcount* is also from the WDI and is the percent of the population living on \$2 a day in PPP terms. *Regulatory barriers* and *size of government* are from the Economic Freedom Network's *Economic Freedom of the World 2012 Annual Report* (Gwartney, Lawson, and Hall, 2012). These indices are from zero to 10 with 10 indicating the most freedom (lower barriers and smaller government size, respectively) but are positively transformed (10 minus the original values) so that higher scores indicate more restraints and larger size, respectively. For poverty headcount, regulatory restraints, and size of government, missing data in intervening years are linearly interpolated to obtain a time series. *Telephones per capita* is from the Banks and Wilson Cross-National Time-Series Data Archive (2012). The data are expressed in units of telephones per thousand people.

Methodology to identify upswings in per capita real GDP

Following Chapter 4 of the October 2012 *World Economic Outlook*, we use the Harding and Pagan (2002) algorithm to identify turning points in LIC real GDP per capita. The algorithm searches for local maximums (peaks) and minimums (troughs) that meet specified conditions for the length of cycles and their phases (upswings and downswings). The only condition we impose is that the cycle (comprising a contiguous upswing and downswing) be at least five years long.

Transformations for the logistic regression

Variables used in the logistic regression appear in one of three forms: (1) initial—the once-lagged, backward-looking five-year average, which captures the average behavior of the variable in the five years before a potential takeoff; (2) contemporaneous—the current year, forward-looking five-year average, which captures the average behavior of the variable in the first five years of a potential takeoff; and (3) change—the difference between the contemporaneous and initial values of a variable as defined here, capturing the average trajectory of the variable from before the takeoff during the first years of a potential takeoff. The moving average in each case is calculated only if there are at least two nonmissing observations for the indicated variable during the window.

Country Groups

Advanced economies comprise the member economies of the Organization for Economic Cooperation and Development before 1990, with the exception of Turkey. The other economies are classified as EMDEs. At any given time, LICs are defined as economies in which output per capita, averaged over the previous five years, is lower than the corresponding low-income threshold, which is time varying. The low-income output per capita threshold represents the bottom 45th percentile of EMDEs' output per capita in 1990 (\$2,600 in 2005 U.S. dollar PPP terms). This threshold is then spliced back for the pre-1990 period and forward for the post-1990 period using the average growth rate of global output per capita during 1950–2011 (about 2.3 percent a year) to obtain the low-income thresholds for the whole sample period. The group of other EMDEs corresponds to the group of EMDEs excluding LICs. To ensure that the results are unaffected by very small economies, the analysis excludes economies whose average 1950–2011 population was less than 1 million. Also, China and India are included in the group of EMDEs but not LICs. See Table 4.6 for the country composition of each of these analytical groupings. For each of the bar charts comparing cases and referents from Figure 4.3 onward, a constant composition sample underlies each of the panels to ensure comparability within the group of cases or referents across time.

The sample of country episodes is divided into four nonexclusive groups according to their economic struc-

ture. In particular, the analysis uses data from the WDI on sectoral value added in local currency at constant prices to classify the country episodes as predominantly agricultural, manufacturing oriented, resource rich, or “other.” The exercise starts by constructing the shares of each sector—agriculture, manufacturing, resources, and other—in total value added and considers nonmanufacturing industry to be resources.³⁶ The 10-year average of these shares is then calculated from the start of a growth episode or from the first year for which a country episode is considered a valid LIC. A country episode is classified as predominantly agricultural if its 10-year average agriculture share is in the 70th percentile for the whole sample of country episodes between 1960 and 2011. Similarly, a country episode is classified as manufacturing oriented (or resource rich) if its 10-year average share of manufacturing (or resources) value added is higher than the 70th percentile for the whole sample of country episodes between 1960 and 2011. The group “other” includes all country episodes that were not classified either as predominantly agricultural, manufacturing oriented, or resource rich.

For country episodes with insufficient data, the grouping is complemented with WDI data on rents from resources. There were a few cases for which data for an industry were available but not their decomposition between manufacturing and nonmanufacturing. In these cases, a country episode was classified as resource rich if its 10-year average resource rents as a percent of GDP were in the 70th percentile for all country episodes between 1960 and 2011.³⁷ A country episode was classified as manufacturing oriented if the 10-year average of its industry sector value-added share was in the 70th percentile of all country episodes between 1960 and 2011 and the 10-year average of its resource rents as a percent of GDP was not in the 70th percentile of all country episodes between 1960 and 2011. Tables 4.1 and 4.2 present the list of LIC takeoffs grouped according to their underlying economic structure.

³⁶Nonmanufacturing industry value added is a proxy for resource-related value added, because this sector includes not only mining and quarrying but also construction and utilities.

³⁷The WDI resource rents are defined as the difference between the value of production at world prices and total costs of production for oil, natural gas, coal, minerals, and forestry. These series are calculated at current prices and are thus affected by changes in international resource prices.

Appendix 4.2. Additional Results and Alternative Measures of Takeoffs

Investment Financing and Macroeconomic Policy in Non-HIPC-Eligible Countries

Two key findings in this chapter are that today's dynamic low-income countries (LICs) achieve sharp reductions in inflation and public and external debt and that they finance their investment growth with a higher share of external non-debt-creating flows. This behavior is in sharp contrast to the previous generation of dynamic LICs, in which inflation and debt levels increased after takeoff, suggesting that the means to finance investment raised macroeconomic vulnerabilities. This section of the appendix assesses whether the improvements in macroeconomic outcomes and investment financing in today's dynamic LICs are broad-based—that is, not limited to the dynamic LICs benefiting from the Heavily Indebted Poor Country (HIPC) Initiative.³⁸

Figure 4.16 suggests that the sharp decrease in inflation and debt levels in today's dynamic LICs is broad-based. The dynamic LICs that did not receive HIPC assistance also experienced sharp drops in inflation and debt within 10 years after takeoff. The higher level of foreign direct investment (FDI) flows for dynamic LICs relative to LICs with weaker growth is also seen for LICs that did not receive HIPC assistance (Figure 4.17). Moreover, recent takeoffs are associated with higher FDI flows compared with takeoffs before the 1990s and relative to LICs that did not take off. Recent takeoffs are also associated with higher aid flows than takeoffs in previous generations, but not relative to the LICs that did not take off.

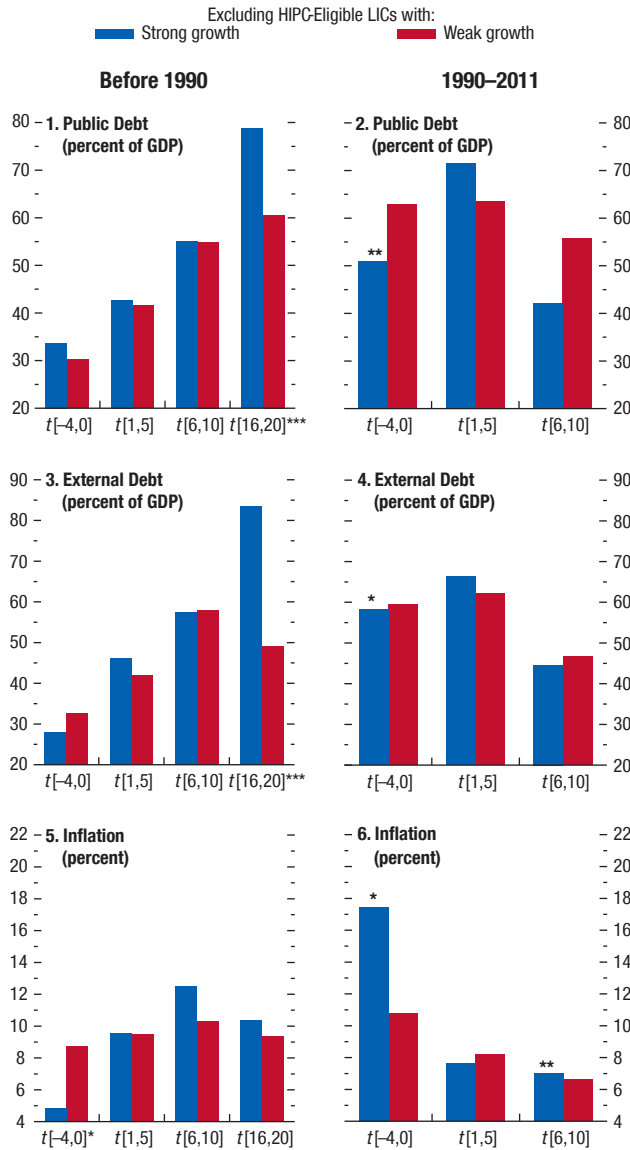

Alternative Samples of LICs

This appendix also explores whether the chapter's findings are robust to alternative samples of LICs. The baseline sample considers a time-varying income threshold, in which a country is defined as an LIC if its average real output per capita during the previous five years is below that threshold. In addition, the baseline sample excludes LICs experiencing or recovering

³⁸The HIPC Initiative was launched in 1996 by the IMF and the World Bank, with the aim of ensuring that no poor country faces a debt burden it cannot manage. To be considered for HIPC assistance, a country must be facing an unsustainable debt burden that cannot be addressed through traditional debt-relief mechanisms and must have established a track record of reform and sound policies through IMF- and World Bank-supported programs. In this chapter, the sample of non-HIPC-eligible countries excludes LICs that were eligible for HIPC assistance at any time.

Figure 4.16. Macroeconomic Conditions for Non-HIPC-Eligible Low-Income Countries
(Median economy; $t = 1$ in the first year of a strong or weak growth episode)

The improvements in macroeconomic stability in today's low-income countries (LICs) are not limited to countries benefiting from the Heavily Indebted Poor Countries (HIPC) Initiative.

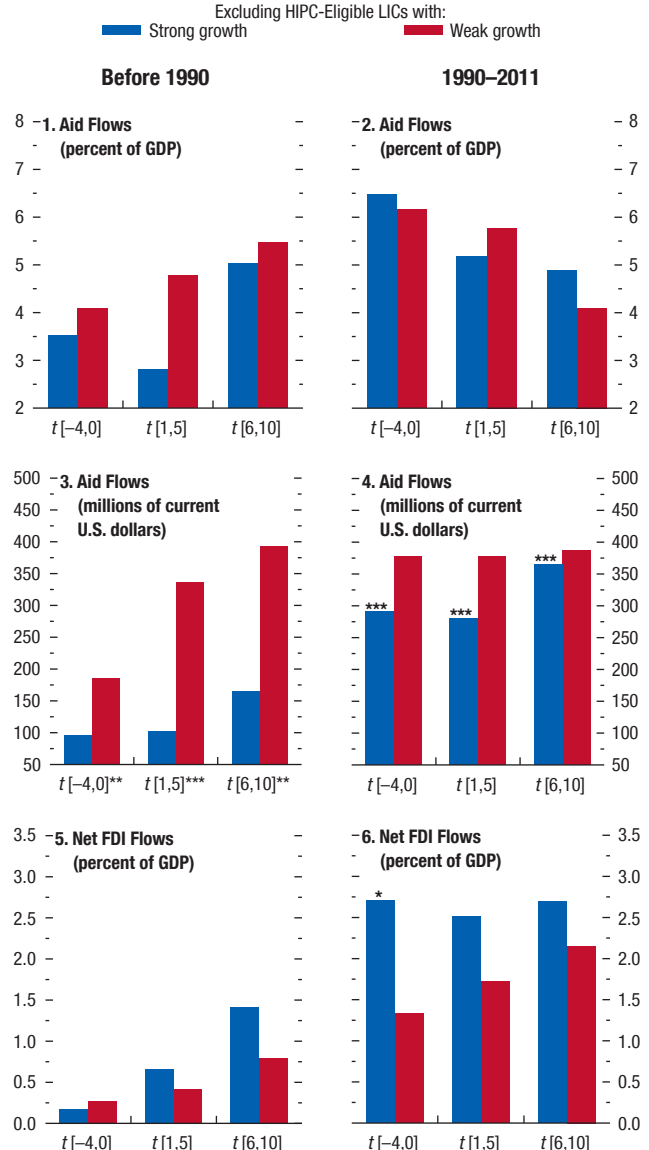

Sources: Abbas and others (2010); IMF, World Economic Outlook database (October 2012); Lane and Milesi-Ferretti (2007) updated to 2011; World Bank, World Development Indicators database (2012); and IMF staff calculations.

Note: Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data. *, **, and *** denote statistically significant difference in distributions (based on the Kolmogorov-Smirnov test) at the 10 percent, 5 percent, and 1 percent levels, respectively. Significance tests on the x-axis are for the difference in the distributions between the groups of strong and weak growth. Significance tests on the blue bars are for the difference in the distributions across 1990-2011 and before 1990 (not shown for red bars). A constant composition sample underlies each of the panels to ensure comparability within the group of strong and weak growth episodes across time for that panel.

Figure 4.17. Aid and FDI Flows to Non-HIPC-Eligible Low-Income Countries
(Median economy; $t = 1$ in the first year of a strong or weak growth episode)

Financing by foreign direct investment (FDI) and aid has also increased for low-income countries (LICs) that were not eligible for debt relief under the Heavily Indebted Poor Countries (HIPC) Initiative.

Note: Economy groups and indicators are defined in Appendix 4.1. LICs exclude countries experiencing or recovering from a serious external or internal conflict at the start of their takeoffs. See the text for definitions of strong and weak growth episodes (takeoffs are strong growth episodes). See Appendix 4.1 for the definition of conflict and the source of the conflict data. *, **, and *** denote statistically significant difference in distributions (based on the Kolmogorov-Smirnov test) at the 10 percent, 5 percent, and 1 percent levels, respectively. Significance tests on the x-axis are for the difference in the distributions between the groups of strong and weak growth. Significance tests on the blue bars are for the difference in the distributions across 1990-2011 and before 1990 (not shown for red bars). A constant composition sample underlies each of the panels to ensure comparability within the group of strong and weak growth episodes across time for that panel.

from a serious external or internal conflict at the start of their takeoffs. This section considers two alternative samples: (1) the baseline sample including LICs experiencing or recovering from a serious conflict; and (2) an alternative sample built with a time-invariant income threshold, in which a country is considered an LIC if its average real output per capita over the previous five years is below \$2,600 in purchasing-power-parity-adjusted constant 2005 U.S. dollars. This threshold corresponds to the 45th percentile of per capita real GDP output for the entire sample of emerging market and developing economies as of 1990. This sample excludes LICs experiencing or recovering from conflict. The chapter's key stylized facts broadly hold for these alternative samples of LICs.

Alternative Measures of Takeoffs

As a robustness check for the baseline results, three alternative measures of takeoffs are considered. First, a growth acceleration, as measured by Hausmann, Pritchett, and Rodrik (2005), is defined as a growth episode that is at least eight years long, during which GDP per capita growth averages at least 3.5 percent, average growth during the episode is at least 2 percentage points higher than during the eight years before the takeoff, and output at the end of the episode exceeds its peak before the takeoff. Second, exclusion of temporary delays corresponds to the baseline sample excluding all growth episodes that start within five years of the end of a previous episode for the same country. Instead of considering those as new episodes, they are considered to be a continuation of the previous episode. Third, a faster growth episode is defined as a cyclical upswing in LIC output per capita that lasts at least five years, with average annual output per capita growth during the upswing of at least 5 percent.

Applying the Hausmann, Pritchett, and Rodrik (2005) algorithm to the sample of LICs results in 55 growth accelerations (31 during 1990–2011 and 24 prior to the 1990s), with a significant overlap with the baseline sample. Excluding temporary delays from the baseline sample reduces the number of episodes from 29 to 24 during 1990–2011 and from 41 to 31 during the period prior to the 1990s. If the cutoff for qualification as a takeoff is raised to 5 percent, the number of takeoffs falls to 17 from 29 during 1990–2011 and to 20 from 41 during 1950–89.

The chapter's findings generally hold for these alternative definitions of growth takeoffs. As in the

baseline, both current- and previous-generation dynamic LICs experienced high investment and national saving rates compared with other LICs. The current account deficits were broadly similar for both generations of dynamic LICs, but a larger share of the deficit was financed by FDI flows for the current generation. Recent LIC takeoffs were also supported by sharp decreases in inflation and public and external debt, which contrasts with the increases in these indicators in the previous generation. Moreover, both current- and previous-generation takeoffs involved stronger export growth, although today's LIC takeoffs have more geographically diversified exports and more competitive exchange rates. Finally, dynamic LICs, especially the current generation, have smaller governments, better infrastructure, and higher human capital levels than LICs with weaker growth.

However, there are two differences between the results using the baseline criteria and those with the alternative criteria using the Hausmann, Pritchett, and Rodrik (2005) methodology. Although income inequality is still lower in dynamic LICs than in LICs with lower growth, current-generation dynamic LICs do not have lower income inequality than those before 1990. Second, the current-generation dynamic LICs do not have stronger political institutions, as measured by the constraints on the executive, than the previous-generation dynamic LICs or the LICs with low growth. There are also two differences between the baseline results and the ones using a higher threshold for takeoff (at 5 percent growth in GDP per capita). We found that recent takeoffs have lower income inequality and stronger political institutions than takeoffs prior to the 1990s, but not relative to the LICs that did not take off. All other stylized facts are broadly similar to those with the baseline criteria.

Appendix 4.3. Logistic Regression and Robustness of the Baseline Results

To simultaneously investigate multiple covariates of the start of strong growth takeoffs in low-income countries (LICs), a logistic regression (logit) model is used. The binary dependent variable is an indicator for a strong growth takeoff:

$$g_{i,t} = \left\{ \begin{array}{l} 1, \text{ if economy } i \text{ starts a strong growth} \\ \text{takeoff at time } t \\ 0, \text{ if not starting or not in a strong growth} \\ \text{takeoff at time } t \end{array} \right\}$$

in which $i = 1, \dots, N$ indexes countries and $t = 1, \dots, T$ indexes time (years). The logit model assumes that the conditional probability of an event ($g_{i,t} = 1$) takes the form

$$P(g_{i,t} = 1 | x_{j,i,t} \forall j \in \{1, \dots, K\}) = \frac{1}{\exp[-(\alpha + \sum_{j=1}^K \beta_j x_{j,i,t})] + 1},$$

in which j indexes the set of K potential covariates, β_j is the coefficient on variable x_j , and α is a constant term (the constant is not reported in results tables to save space). The models are estimated by maximum likelihood.

To help assess the performance of the logit models, statistics from the receiver operating characteristic (ROC) curve defined by the estimates are shown. The ROC curve summarizes how well the model is able to explain the occurrence of a success (takeoff) and a failure (no takeoff). See Berge and Jordà (2011) for an in-depth discussion of the interpretation of ROC statistics. In brief, the ROC captures the relationship between the true positive rate, TPR(π), or share of correctly classified takeoffs for the threshold probability π , and the false positive rate, FPR(π), or share of incorrectly classified nontakeoffs. The area under the ROC curve (AUC) is a global measure of the performance of different logit models—the most accurate model shows the largest AUC and the least accurate shows an AUC close to one-half. To make the classification using the model practicable, an optimal threshold probability needs to be selected from the large set of possible thresholds characterized by the ROC curve. Because of its simplicity, the so-called Youden index and its associated cutoff threshold, π^* , are used. The Youden index (J) is the difference between the true positive rate and the false positive rate. Then π^* is the value of π that maximizes $J = \{TPR(\pi) - FPR(\pi)\}$.

Robustness to Alternative Specification and Definition of Takeoff

The analysis considers a specification that adds decadal dummies to the baseline and two alternative definitions of takeoff, one drawing on the Hausmann,

Pritchett, and Rodrik (HPR) definition of growth acceleration (2005) and the second using a fixed income per capita threshold below which a country is classified as an LIC set at \$2,600 purchasing-power-parity-adjusted 2005 constant U.S. dollars, which is roughly the 45th percentile of income per capita in 1990 among emerging market and developing economies (see Appendix 4.2 for further details). As shown in Table 4.7, the baseline findings are robust to the alternative specification and definition. When the HPR-derived definition of takeoff is used, the same general pattern of coefficient signs is seen, although they are statistically insignificant for the structural conditions. This insignificance may reflect the lower incidence of HPR growth accelerations in the full sample and their greater concentration in the sample since 1990. The model based on the HPR definition is not estimable before 1990 because of the paucity of growth accelerations among LICs during that period.

In other checks (not shown), we also found our baseline results to be robust to including serious conflict cases and to merging takeoff episodes that are within five years of each other. The latter check reduced the number of takeoffs in the logit sample to 17 from 28, so the results should be interpreted with caution.

Robustness to Alternative Estimation Methods

Because growth takeoffs are comparatively rare events (with a less than 5 percent unconditional probability of occurrence in a year), alternative estimators that are more robust to the problems associated with rare events in the logit model (for example, attenuation bias in small samples) were also tried. In particular, the baseline model was also estimated using: (1) Firth's (1993) bias-reducing transformation of the log likelihood; (2) King and Zeng's (2001) procedure for the generation of approximately unbiased coefficients in logit modeling; (3) the complementary log-log transformation, which helps account for skew in the distribution of the dependent variable; and (4) the random effects logit model. As seen in Table 4.8, the signs and magnitudes of the logit coefficients are similar across estimation methods (full sample shown).

Source: IMF staff calculations.

Note: The dependent variable is a dummy variable for the start of a new growth takeoff. Indicators (variables) are defined in Appendix 4.1. Heteroscedasticity and autocorrelation within country robust standard errors are in parentheses under the logistic regression coefficient estimates. *, **, and *** denote significance at the 10 percent, 5 percent, and 1 percent levels, respectively.

¹EMDEs = emerging market and developing economies.

²AUC = area under the receiver operating characteristic curve.
